From Nov. 23rd, 1908, to May 22nd, 1909, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 402. The total theoretical teaching was required. He remembered, too, that Sir John Simon defended this view. It was largely owing to Sir John Simon that the Diploma of Public Health was instituted, and it was undoubtedly owing to him that the Council got complete control of it. He held that it was not to be a mere slight addition to the knowledge of hygiene that a man acquired in an ordinary medical course. It was to be altogether something special, something quite on a different plane altogether. Everyone connected with public health whom he knew would entirely object to the shortening of the time which must elapse before the diploma was granted. If the time was whittled down to nine months there was little between that period and six months. It would then become a diploma which every medical student might take. He spoke for every member of the Public Health Committee when he said that they entirely objected to anything that would lower the amount of work which was required for it. The amount of work which students did working with medical officers of health should be increased rather than diminished. Sir Charles Ball had explained how the nine months were introduced into this matter. It was with great unwillingness that the chairman of the Public Health Committee of that day, and the members of it, agreed to the introduction of the nine months. It was introduced on the understanding that it was to apply to medical men coming from abroad alone. It was only on account of the necessities of the public service that the committee consented to the concession. Therefore the Council ought not to extend the concession, to which he objected on the grounds of the public interest.

Sir THOMAS MYLES expressed sympathy with the motion of Mr. Thomson. Dr. McVail had said that the nine months concession had been made for the medical man whose work lay abroad. However, it was the case that the man who had spent 20 years abroad had had no opportunity of acquainting himself with modern conditions of work bearing on public health. On the other hand, an enormous amount of public health work was done in the hospitals. The modern student had a very good training in clinical bacteriology and chemistry. This student was to be penalised. The man who had been in the bush in India was to have the advantage of the three months' concession. The case of a young graduate could not be ignored from the monetary point of view. He was bound to be spending money in order to defray his cost of living during the three months. He would join his voice in the protest against any ornamental additional to the time. His objection was to the existence of any ornamental portion of the curriculum.

Sir THOMAS FRASER said it would be extremely unfortunate if at this time the Council reduced the qualifications for this important branch of the profession. They in the north would deprecate any lowering of the standard in this respect.

Mr. THOMSON then moved as an amendment that the report be referred back to the committee. He emphasised the point that it was not his intention to lower the standard. It had got nothing to do with the standard; it was plain, straightforward common sense. If the course could be done in nine months the members of the Council need not demand 12. He knew from those with whom he had discussed the matter that the men found the delay hang heavy on their hands. He should like to have some definite statements with regard to what were the requirements of the six months at the laboratory. Was a man to attend during all the hours of every day? For the reason that he believed the curriculum could be done in the shorter time he thought the men who were taking the diploma had just cause of complaint.

Sir C. NIXON formally seconded the amendment.

Sir JOHN MOORE remarked, in replying to the discussion, that it was a very remarkable circumstance that everyone who was opposed to the adoption of this report was not the holder of a diploma of public health. He himself happened to be the oldest Diplomate of Public Health. He strongly held that the nine months' period was too short. The circumstances which had been revealed by the debate showed how unfortunate it was that any diminution in the Council's requirement should have been made in the case of army medical officers. Sir C. Nixon had quite unconsciously misled the Council a little when he spoke of the position of medical officer of health in Ireland and its requirements. The dispensary medical officers were forced by Act of Parliament to be the medical officers of health for their respective districts. In no instance was it necessary for them to have the additional qualification. When a medical man sought the post of medical officer of health for a district with a population of not less than 50,000 he must produce the additional qualification. He believed that for such a man even 12 months were too short to put him in a position to do his work thoroughly. Sir Thomas Myles had spoken of the clever young student being penalised. The Council was not penalising anybody. It merely wanted to secure that a man should spend 12 months in the study of public health. If the curriculum was completed in nine months after the ordinary medical degree had been obtained the young medical man had time left to prepare for his examination. No man after he took the final examination in his medical course did start studying for the Diploma in Public Health at once. He generally went off on holidays or took six weeks off at Christmas. Thus there might be three months taken away from the 12. It had been remarked in the course of the debate that students were taught bacteriology and chemistry. The students were taught chemistry in their first year and their knowledge of bacteriology was, on the authority of the Council's examiners, often deficient. He hoped that the Council would reject the amendment by an overwhelming majority.

Sir C. NIXON asked leave to make one observation before the amendment was put from the chair. He drafted the syllabus of the curriculum for the Royal University of Ireland and it was adopted. The idea in the mind of the University was that there ought to be two grades of diploma established in connexion with it—a lower grade of diploma representing the requirements of the Council, which would be quite sufficient for the ordinary class of medical officers, and a higher grade of degree, a Doctorate of Public Health. The latter would be specially applicable to public health officers charged with the care of a population of 50,000 or more. He thought that the Council in making regulations for its diploma ought not to be too exacting. It ought to legislate for the rank and file of the profession and not set up an impossible standard. He was satisfied with the requirements necessary in the nine months' curriculum.

The amendment to refer the report back to the committee was lost by a large majority and the report was adopted

Penal Cases.

Penal cases occupied the rest of the sitting.

The Council resumed consideration (adjourned from Nov. 27th, 1908) of the facts proved against William John Watson, in regard to whom the Dental Committee at its meeting on May 24th, 1909, drew up a supplementary report. In it is stated that the committee find upon the evidence that:—

> An unqualified man named Herbert Arthur Frank Potter, who had for some years been in the employment of, and represented himself to be, the said William John Watson, attended a patient of the said William John Watson in November, 1908, but he did not actually perform a dental operation, and the charge made against the said William John Watson of covering an unregistered practitioner was not proved to the satisfaction of the committee, nor was the charge of advertising in the name of another practitioner brought home to the said William John Watson. On the other hand, no evidence other than his own statement was presented to the Committee as to the conduct of the said William John Watson since the matter was before the Council at their session in November last. It was not alleged that any [illegible] had been issued by the said William John Watson in [illegible] ot regard the evidence presented by [illegible] is to his conduct in the interval as satisfactory, seeing that he had still some connexion with the said Potter, who to his knowledge was in the employment of a company called Booth and Co., Ltd., consisting of unqualified persons who continued to advertise from the addresses where Mr. Watson formerly carried on business.

Mr. WATSON attended in answer to his notice, but he was not accompanied by counsel or solicitor.

The complainants (the British Dental Association) were represented by Mr R. W. Turner, instructed by Messrs Bowman and Curtis-Hayward.

Mr. WATSON made a statement on his own behalf and said that he was only anxious to clear himself of this charge. He admitted that he had committed an error of judgment in this case. He would take care not to repeat it.

After deliberation *in camerâ*,

The PRESIDENT said: Mr. Watson, the Council has again given careful consideration to the two reports of the Dental Committee, and has deferred the further consideration of your case to November next, when you will be required to be present in person and to produce satisfactory evidence, and *not merely a personal statement, as to your professional good conduct in the interval, with particular reference to your* [illegible]

[illegible] Nov. 27th, 1908) of the facts proved against Charles Morgan, in regard to whom the Dental Committee at its meeting on Monday, May 24th, 1909, drew up a supplementary report.

In the supplementary report the committee found upon the evidence that :—

> Notwithstanding the undertaking give[illegible] to discontinue all advertisements, the s[illegible]

Mr. Morgan attended in answer to his notice, accompanied by Mr. Arthur P. Poley, his counsel, instructed by Mr. H. Morgan Rees, solicitor, Cardiff.

The complainants were the British Dental Association and were represented by Mr. R. W. Turner.

Mr. POLEY stated on Mr. Morgan's behalf that a letter had been received from the secretary of the London and Provincial Advertising Agency, Limited, consenting to withdraw the advertisement from the curtain at the Empire Theatre, Newport, on certain terms, and asked that the Council would postpone judgment for six months in order that Mr. Morgan might have an opportunity to show that this had been done.

After deliberation *in camerâ*,

The PRESIDENT said: Mr. Morgan, the Council has again given careful consideration to the reports of the Dental Committee, and has deferred the further consideration of your case to November next, when you will require to be present and to offer satisfactory evidence other than your own statement as to your professional good conduct in the interval, with particular reference to your promise to discontinue the issue, direct or indirect, of all advertisements.

The Council then considered the report of the Dental Committee on the charge against Samuel David Davis. The committee found that the following facts were established by the evidence ;—

> [illegible] agreement to devote his whole time to such service and to carry out the directions of the said F W. Bradley or other the directors of the company. The remuneration paid by the company to the said Samuel David Davis is £4 4s. a week and 5 per cent commission on all cash received in respect of orders taken by him. F. W. Bradley, Ltd , is a company incorporated under the Companies Act to take over and carry on a dental practice formerly carried on by *one, Frederick William* Bradley, at 6, Market-street, Wisbech, the Castle, Wisbech, and numerous branches in the eastern counties. The capital of this company is £20 000, the whole of which was issued as fully paid up, and no part of which was paid up in cash; 19,733 £1 shares are owned by the said F W Bradley, 101 by Mary Bradley, his wife, 101 [illegible] Bra[illegible] Bra[illegible] dire[illegible] said [illegible] der [illegible] Wisbech, was carried in the name[illegible] *Claud L. Sutton, surgeon-dentist.* [illegible] but neither of them has practised [illegible]

Mr. Davis appeared in person.

The complainants, the British Dental Association, were represented by Mr. R. W. Turner.

[illegible] his great [illegible] inform you that the Council have given careful consideration to the report of the Dental Committee and that they have judged you to have been guilty of [illegible] in a professional respect an[illegible] erase from the Dentists Re[illegible] Davis.

The Council then took up the consideration of the case of Frederick Joseph Whitehead, which had been referred to the Dental Committee. The committee found that the following facts were established by the evidence :—

> The said Frederick Joseph Whitehead was registered in the Dental Register on the 31st of December, 1878, as "In practice before July 22nd, 1878." His address in the Register for 1909 is Market-street, Wisbech, Cambs. *The said Frederick Joseph Whitehead knowingly and wilfully* [illegible] their employ.

Mr. Whitehead *did not attend nor was he represented* by counsel or solicitor.

The complainants, the British Dental Association, were represented by Mr. R. W. Turner, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Council deliberated on the case *in camerâ*.

When the public were readmitted the PRESIDENT said: I have to announce that the Council have given careful consideration to the report of the Dental Committee and have judged Mr. Frederick Joseph Whitehead to have been guilty of infamous and disgraceful conduct in a professional respect and have directed the Registrar to erase from the Dentists Register the name of Frederick Joseph Whitehead.

The case of Reuben Davis was next considered, in which case the Dental Committee had reported as follows :—

> The said Reuben Davis was registered in the Dentists Register on *Dec. 31st, 1878,* as "in practice before July 22nd, 1878," and his ad[illegible] Sessions of stealing [illegible] pairs of forceps and was sentenced to three months' hard labour. That on Sept. 2nd, 1908, the said Reuben Davis was convicted at the Gloucester Petty Sessions of stealing a watch, money, &c., and was sentenced to two months' hard labour. That on Dec. 31st, 1908, the said Reuben Davis was convicted at the Wigan Petty Sessions of stealing one shirt, two collars, one front, four collar fronts, and one pair of cuffs, and was sentenced to 14 days' imprisonment. The evidence before the committee consisted of certified copies of the several convictions.

Mr. Reuben Davis did not attend nor was he legally represented.

The Council having deliberated in camerâ,

The PRESIDENT said: I have to announce that it having been proved that Reuben Davis has been convicted of various misdemeanours as set forth in the report of the Dental Committee, the Registrar has been directed to erase from the Dentists Register the name of Reuben Davis.

The Council then proceeded to the consideration of the case of Stanley Bennett Wakefield. In this case the Dental Committee submitted the following report. The committee found that the following facts were established by the *evidence :—*

> [illegible] the said Stanley Bennett Wakefield w[illegible] police court of illegal pawn-in[illegible] the value of the pawned go[illegible] imprisonment, and that he [illegible] fraudulent claim.

Mr. Wakefield did not attend nor was he represented by counsel.

The complainants (the British Dental Association) were represented by Mr. R. W. Turner.

The Council having deliberated *in camerâ* the PRESIDENT announced the decision of the Council as follows: "I have to announce that it having been proved that Stanley Bennett Wakefield has been convicted of a misdemeanour the Registrar has been directed to erase from the Dentists Register the name of Stanley Bennett Wakefield."

The Council thereafter considered the case of Thomas Parkins. The report submitted by the Dental Committee was as follows:—

> The committee find that the following facts were established by the evidence. The said Thomas Parkins was registered in the Dentists Register on Dec. 30th, 1878, as "in practice before July 22, 1878." The address in the Register for 1909 is 1, Bexley-square, Salford, Manchester. The said Thomas Parkins lives at Salford, but a dental practice is carried on in his name at Sharrow Head House, Sharrow Head, Sheffield, by his son Charles Henry Parkins, who is an unregistered person who habitually performs dental operations there and signs receipts for accounts paid by patients for work done by him in the name of the said Thomas Parkins.

Mr. Parkins attended in person.

The complainants (the British Dental Association) were represented by Mr. R. W. Turner.

Mr. PARKINS addressed the Council. The business he had conducted, he said, was his own. He admitted his son assisted him in the business under his supervision. He had been teaching his son the business for the last four or five years. He was very sorry the complaint had been made against him. He was totally ignorant of the fact that he was doing anything wrong by employing his son to assist him.

The Council having deliberated *in camerâ*,

The PRESIDENT said: Mr. Parkins, I have to inform you that upon the facts found in the report of the Dental Committee the Council have judged you to have been guilty of infamous or disgraceful conduct in a professional respect and have directed the Registrar to erase from the Dentists Register the name of Thomas Parkins.

Mr. PARKINS: I am sorry to hear that. I think at my time of life it is rather cruel after having been on the Register since the passing of the Act. Is that the best or the worst you can do for me? I feel it very much. Excuse me, gentlemen, making these remarks. I never knew I was doing any wrong. I was totally ignorant of it. I have had a large family to bring up and I have had a great deal to do. It is very hard on me to be removed from the Register now—very hard indeed. You might have allowed me to have one place open.

The PRESIDENT: The case is now closed.

Mr. Parkins then left the Council Chamber.

The Council then considered the case of Thomas Torrens McKendry, registered as of 39, Wellwood-road, Goodmayes, Ilford, Essex, M.B., Bac. Surg., 1894, R. Univ. Irel., who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

> That you have knowingly and wilfully on various occasions, and in particular on Feb. 20th, 1909, assisted one E. C. Dalby, a person not registered as a dentist, in carrying on practice as a dentist by administering anæsthetics on his behalf to persons coming to him for treatment and that in relation thereto you have been guilty of infamous conduct in a professional respect.

Dr. McKendry attended in person.

Mr. Chatelain, the complainant, also attended and called evidence.

Mrs. FLORENCE JANE CHATELAIN, wife of the complainant, said her husband received information to the effect that Dr. McKendry was giving an anæsthetic to a Mrs. Flynn. Witness proceeded to Dalby's house and saw both Dr. McKendry and Mrs. Flynn leave. She knew that Dr. McKendry was not Mrs. Flynn's usual medical adviser.

Mr. WILLIAM RAYMOND BRYAN, secretary to a company, said he had heard that Dr. McKendry had given an anæsthetic in Dalby's house.

Mr. LUSHINGTON: But do you know anything about it except what you have been told?—No.

Did Dr. McKendry tell you?—No.

Mr. CHATELAIN read a declaration by Mr. Richard Henry Stevens, L.D.S. R C.S. Eng., a registered dentist of Ilford, who said he had warned Dr. McKendry against assisting Mr. Dalby by giving anæsthetics to his patients.

Dr. McKENDRY made a statement that he gave gas on the particular occasion alluded to. He was medical adviser to the family of Mr. Dalby, and on one occasion when he visited Mr. Dalby's house he was suddenly asked to give the gas. He was taken by surprise, and, without reflection, unfortunately he did it. He had afterwards told Mr. Dalby that he was annoyed at him for asking him to do this.

After deliberation *in camerâ*,

The PRESIDENT said: Mr. McKendry, the Council has found that the facts alleged against you in the notice of inquiry have been proved to its satisfaction. Before we proceed to judgment we understand you may desire to make some appeal to the Council, and therefore I now give you an opportunity of saying something before the Council proceeds to the next step of pronouncing judgment.

Dr. McKENDRY expressed his very great regret. He was extremely sorry at what had taken place. He gave the Council an assurance that he would never again transgress against the resolutions of the Council in regard to the administration of anæsthetics for unregistered dentists.

After a further deliberation *in camerâ*,

The PRESIDENT said: Mr. McKendry, the Council has postponed judgment until the November session, when you will be required to attend in person and to produce evidence, more particularly from medical colleagues in your neighbourhood, as to your professional good conduct generally in the interval, and in particular that you have not repeated the offence of which complaint has been made.

The Council adjourned.

SATURDAY, MAY 29TH.

The Council resumed its sittings to-day at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

A Committee on Anæsthetics.

On the motion of the PRESIDENT, it was agreed—

> That a committee be appointed to consider the proposals for legislation on the subject of anæsthetics which have been or may hereafter be put forward, to make such representations on behalf of the Council, to the authorities concerned, as may be deemed necessary, and to report to the Council on the position of the subject at the November session. That the committee consist of the President, Mr. Morris, Mr. Tomes, Mr. Hodsdon, and Sir Charles Ball.

The Council then adjourned until Tuesday, June 1st.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 4th, 1831.

There was presented also a case of

PALSY OF THE WRISTS FROM LEAD.

The case was precisely like others that I have alluded to, in the course of the winter, in its symptoms; and it was cured in the same way—by the application of electricity. I never had recourse to electricity in this complaint before this winter, and I certainly have had every reason to be satisfied with it. The man got so well in a short time that he felt able to go to his work, and had no desire to stay here any longer; indeed I believe I may say he got perfectly well. The electricity was diligently applied every day to the wrists, and in the form of sparks. I believe I mentioned before that one man in the hospital satisfied himself that sparks did much more good than shocks in his case. This man was admitted on the 3d of February. He had been working among white lead for nine weeks; his wrists had been paralysed for a fortnight; he was in a few days better. On the 11th he was much better; and on the 17th March he was presented perfectly well.[1]

USE OF THE WHITE AGARIC IN NIGHT PERSPIRATIONS.

DR. BURDACH, of Triebal, has confirmed the opinion, that the white agaric possesses in small doses the property of arresting excessive nocturnal diaphoresis. It is best given to the extent of from four to six grains in the evening, and it may be repeated in the day-time, if the patient be not of an irritable habit. It may be given in the form of a bitter extract made into pills. It has also been successfully used in habitual diarrhœas, in combination with alumn or kino.

[1] Excerpt from Clinical Lecture delivered at St. Thomas's Hospital, by Dr. Elliotson on March 21st, 1831.

THE LANCET.

LONDON: SATURDAY, JUNE 5, 1909.

The Report of the Education Medical Officer of the London County Council.

THE important and highly practical question of the provision which must be made for the effective treatment of the diseases of school children should rapidly become ripe for complete solution, so various and numerous are the aspects from which it is being observed; and the considerations with regard to it which we have from time to time put forth, or which have been suggested by correspondents, can now be reviewed by the light of an official report of a highly interesting and instructive character, which has been made to the Education Committee of the London County Council by its medical officer, Dr. JAMES KERR. This report covers a period of 21 months, having been carried beyond the ordinary annual limit in order to bring it into unison with the reports of other authorities, and hence it extends from March 31st, 1907, to Dec. 31st, 1908. It shows that at the end of 1908 the medical staff of the Council numbered 52. In addition to Dr. KERR himself there was an assistant medical officer giving his whole time, there were two assistants giving half-time, and eight giving quarter-time, of whom three were women. The statutory medical inspections were carried out by a temporary staff of 16 school doctors, each in charge of a district, and having one or more assistant school doctors, of whom there are 24. It has been decided to increase the staff by the addition of 16 assistant school doctors in the summer and by another 16 in 1910, so that ultimately there will be 72 members of this temporary staff giving quarter-time, and each appointed for a term of three years. For the routine inspection the teachers are asked to name all the children who are known to them as presenting any abnormality except defective vision; and the doctor sees these children and notes any cases presenting defects of hearing, brain, speech, limbs, or nutrition, and leaves a card with the teacher for each child requiring treatment. The doctor then goes over the school and notes its general condition and that of the children, the hygiene of the work, and any other matters which affect the health of either teachers or scholars, as well as the general development of the latter. The routine with regard to the eyesight of the children may be specified to show the thoroughness of the procedures employed. The vision of all the children is tested once in 12 months, in one-half of the schools in April, and in the other half in September. The preliminary test is done by the teacher, and the names of all children in Standards I., II., III., and IV. whose vision is $\frac{6}{12}$ or worse, and of children in standards V. and above, whose vision is $\frac{6}{9}$ or worse, are placed on a form provided for the purpose. When the doctor visits the school he examines these children and gives the teacher a red or a green card, according to the amount of defect, for each child who should seek advice. These cards are at present distributed to the children a few at a time, "so as not to cause inconvenience to the hospital authorities," a striking commentary upon the suggestion that these same hospitals might deal with the cases collectively.

The general results of the medical examinations are stated in respect of two periods, one of 12 months from April 1st, 1907, to March 31st, 1908, the other of nine months, from April 1st to Dec. 31st, 1908, and it is not quite clear to what extent the figures may cover the same children. During the first period there were 270,749 children on the roll, and during the second 112,685; but it does not appear whether a correct total for the whole period would be reached by adding these figures together. In respect of the morbid conditions found, however, the totals may almost certainly be added, and they come out as follows. 50,422 children were specially examined and 3601 were reported by their teachers on account of defective vision (apart from the results of the general vision testing mentioned above), 3137 on account of defective hearing, 2356 for imperfect speech, 6278 for physical and 2406 for mental defect. Of these totals the doctors reported that 11,678 children "*required treatment urgently*" and that 886 required "transference to a special school." During the same period 4022 children were selected individually from their classes and reported on for external (and presumably in many cases infectious) diseases of the eye, 5552 for throat or nose affections, 1698 for ear disease, 306 for "excessive dirt," and 2713 for "other defects." The results of the systematic vision testing are rendered somewhat difficult to analyse by the fact that they also deal with two successive periods which must to some extent embrace the same children, and we will therefore refer to the second period only, the last nine months of 1908. In the returns for this period the higher elementary schools are included, and the figures embrace 313,415 children, of whom 29,326 were reported as having defective sight by their teachers, whose opinions in 20,584 of the cases were confirmed by the ophthalmic surgeons. Dr. KERR estimates the number of cases of defective sight among the whole of the London school children at about 60,000. He also declares that there is a great prevalence of dental caries, for the treatment of which the existing provision is wholly inadequate; that nearly 3000 children are suffering from ringworm, with a consequent loss of some £6000 a year in grant; and that about 7500 children are suffering from suppurating or discharging ears, a condition which, if neglected, frequently produces deafness or defective hearing, and sometimes consequences dangerous to health or life. He also points to a large number of children living in insanitary conditions and to numerous cases of tuberculosis (numerous in the aggregate but not when regarded as a percentage of a vast crowd), in which the consequent debility renders the pupils unable either to profit by instruction in school or to continue their attendance without further deterioration.

In view of the mass of disease and misery thus disclosed to view, it is obviously impossible for the community to rest content with a policy of inaction or with anything short of an endeavour to rescue as many as possible of these poor children from the dangers by which they are surrounded, and which are increased to an indefinite degree both by the aggregation which the maintenance of the school system requires and, especially in the case of defective vision, by the very processes of teaching. The children have a definite moral right to be protected against injury forced upon them under the form of benefit; and, both for their own sakes and for the sake of the generation in which they will eventually take their places as mature elements, it is necessary that the physician should play his part, and equally necessary that in so doing he should receive the hearty coöperation of the teacher. Dr. KERR assigns weighty reasons for his belief that the necessary protection can only be afforded by placing the whole life of the child during school age, say from three to 15, under the control of a wisely guided education authority, by which all relating to the feeding, teaching, cleansing, medical treatment, or social protection of children, when these matters become a public care, would be administered, and by which the overlapping of authorities, with its consequent costliness and inefficiency, would be avoided. It is manifest, even from the figures which we have quoted, that the medical treatment is an immediately pressing matter, and we have already referred to the apprehension expressed by many correspondents that an attempt would be made to throw this work upon the hospitals and to add to the existing "abuses" of these institutions a new one which would cast all others into the shade. We are informed that certain London hospitals have already been approached by the London County Council and are even now coquetting with that body in the hope of effecting some "arrangement"; and we hear also that a prospect of pecuniary subsidies has been held out to the hospitals in question. Some day, perhaps, we may come to the municipalisation of the hospitals, and then if the community benefits the medical profession may expect to benefit in proportion. But we have not yet arrived there, and it is the duty of our hospital authorities to protect the charities and the medical profession from exploitation. The matter is one on which the opinion of the medical profession will, we think, be unanimous, and we hope that the staffs of the great hospitals will lead the way in giving expression to that opinion and in emphatically declining to lend themselves to any premature scheme. The necessity for systematic medical care of the children has largely arisen from Parliamentary enactments, the full effect of which, it may be freely admitted, was not foreseen by those who passed them, but for which, nevertheless, the nation is responsible in such a sense that it should not be permitted to cast the consequent cost upon the shoulders of charities maintained by voluntary contributions for the accomplishment of totally different purposes. The business of our great voluntary hospitals is to deal with severe disease or accident among the poor, to promote the growth of medical and surgical science, and to afford the conditions necessary for the conduct of medical education. To employ hospital officers in the routine treatment of thousands of cases of school illness would be to divert them from their proper duties, and cannot be done without serious injury to science and to the public The medical profession has a distinct claim to receive suitable recompense for the work; and the endeavour to cast it upon the already over-burdened and often inconveniently situated hospitals needs only to be understood in order to be condemned. There is no doubt, however, that such an endeavour has at least been in contemplation, and the profession should lose no time in expressing its views upon the subject.

◆

The Early Recognition of Uterine Cancer.

THE Council of the British Medical Association has recently approved of appeals to promote the earlier recognition of cancer of the uterus being issued to medical practitioners and to midwives and nurses. In these appeals, which were published in the issue of THE LANCET for May 15th, p. 1408, the fact is pointed out very strongly that cancer is at first a purely local disease and one curable by operation. The responsibility which a medical practitioner incurs if he fails to make a physical examination in any case presenting symptoms of cancer is very great, and the treatment of such symptoms without an examination is quite unjustifiable. Unhappily, in only too many of these cases the fault lies with the patients themselves. It is not that the medical man fails to recognise the presence of the disease, but that the patient postpones seeking medical advice until all possibility of the complete removal of the growth has gone. The results which recently have been obtained by the adoption of the more radical and extensive method of removal of the uterus by the abdomen are most encouraging. Not only has the percentage of operable cases increased to a very marked degree, but the total number of cases cured—that is, which remain free from recurrence after five years—is very striking. If it were possible to ensure that all women who present any symptoms of uterine cancer should seek medical advice at the very earliest opportunity after the appearance of such symptoms, there can be no question that even better results could be obtained. Whatever the future may have in store with regard to other possible means of treating or of preventing cancer, the removal of the growth by operation is often the only method of cure applicable at the present time.

The crusade which has been carried out in Germany for the purpose of disseminating amongst the laity a better knowledge of the early symptoms of this dread disease has met with most encouraging results. Unfortunately, in this country the method which the German authorities have adopted of publishing short paragraphs in the lay press, for the purpose of instructing all women in the early symptoms of uterine cancer, is quite impracticable. In these circumstances the plan adopted by the Council of the British Medical Association in issuing appeals addressed to medical men, and more particularly to midwives and nurses, is no doubt the best that can be devised. At the same time we cannot but regret that the committee appointed by the

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 13th, 1909.

> "See the wretch that long has tost
> On the thorny bed of pain,
> At length regain his vigour lost
> And breathe and walk again"—GRAY.

AGAIN we appeal to the benevolent public on behalf of the Metropolitan Hospital Sunday Fund and of those great institutions for the aid of which it was established nearly forty years ago. We address ourselves to those whose forefathers founded the hospitals of London, and bequeathed them to their descendants as an incentive to charity and as an example to the world of what the goodwill of great-hearted men and women can achieve on behalf of their fellows; and we have confidence that the response, as in past years, will be a generous one. The hospitals and their necessities are always with us. The Metropolitan Hospital Sunday Fund is no new institution. Only those who are grey-headed among us can rely upon personal recollection for the story of its inception, and that which, no matter its urgency, is ever before our eyes, or of which we are reminded with regularity at stated periods, is apt to be overlooked in favour of newer or more insistent claimants of our attention. We ourselves are repeating demands and are possibly about to lay stress upon arguments which we have urged before; but we hope that our readers will not forget that the need for their assistance is never less but rather greater as the years move on. The changes that they have recently brought about, and which they continue to bring, if we pause to realize them, make ever for increased efficiency, and call for means to cope with the needs of a larger but not less necessitous population. For more than twenty years the proprietors of THE LANCET have caused this Annual Supplement to be devoted to pleading the cause of the Fund, and ever since its first appearance it has been regarded as a feature of special importance in the annual programme of their paper. No one took a keener interest in it and in the success of the Hospital Sunday Fund than Mr. Thomas Wakley, whose death took place last March, after he had been sole Editor for but two years. Before this he had been joint Editor with his father since 1887, and from that date a special supplement issued, as to-day, on behalf of the Metropolitan Hospital Sunday Fund has been published in our columns.

Mr. Wakley was also a member of the Committee of the Metropolitan Hospital Sunday Fund, as were his father and uncle before him, and like them took a practical and personal part as well as a keen interest in its organization. So that in him the hospitals as well as ourselves have lost during the past year a firm and helpful friend.

Whatever blows, however, time may inflict upon us, and whatever changes we may have to record from year to year when we survey the incidents that the past twelve months have brought about, the continuity of the work of the hospitals around us in the metropolis is never broken, the stream of human suffering flows towards their gates in unabated volume, and the Metropolitan Hospital Sunday Fund has ever to reiterate its claim for that financial help without which good will and good work can effect but little. It appeals to all. Wealthy friends help it each year to maintain its high level of success; but it must be on the countless smaller offerings of the many that in the first place it should rely. The tables which we publish include the names of generous individuals who have given thousands of pounds in single donations, and they are names which should never be forgotten when the hospitals and their supporters are spoken of. It is to others, however, rather than to these that we address ourselves in these pages. They know the circumstances of the hospitals and the meaning of incessant strain upon narrow means, and their minds will be made up to assist without needing to be stimulated by us. It is therefore more especially to the wider mass of readers that we appeal on "Hospital Sunday." On that day, or on the preceding Saturday if they be of the Hebrew Faith, we urge them to give their alms at whatever place of worship they may attend, and we ask them to do this to the full extent of their ability. We also express the hope that they will not allow any of their friends, who may not intend to be present at a place of worship where a collection is made, either to forget or to ignore the appeal. Every shilling is wanted, and every shilling denied must mean of necessity some corresponding denial of relief to a poor sufferer, although neither he who withholds his gift nor anyone else can ever gauge or define the effect of the omission. It is for the lessening of human suffering that the money contributed is bestowed, and of suffering not limited to the bodily pain felt by the individual who seeks medical or surgical aid at the hospital. He or she in any given instance may be the father or mother, son or daughter, on whom the household depends to earn the wage that keeps the wolf from the door. If he be a child, he will be one who some day will need to win for himself a living which will probably be proportionate to the health and strength which he enjoys, and the money spent on alleviating the bodily ailment of such a child in the present will carry with it the saving of him from more bitter pain in the future. If it helps him to grow up to sound manhood, as well it may do, thereby enabling him to become a healthy and useful citizen, it will prove itself an investment on behalf of the community bringing in profit a hundredfold.

The State and the Health of its Citizens.

This aspect of the provision of medical aid for those who cannot afford to pay for it well merits the consideration of those who are already aware of the benefit which the hospital confers on the individual in alleviating his personal pain and in restoring him to health. It has been brought before us during the past few months by the publication of the Report of the Royal Commission on the Poor Laws and the Relief of Distress, which, while concerning itself mainly with the medical assistance rendered by the community to the individual and paid for out of the rates, has also had to consider the present and future condition of hospital work. The Report contains valuable criticism of the system under which rate-provided and voluntary medical relief are furnished to the necessitous, and in that criticism and in the suggestions made for the co-ordinating and organizing of both the rate-provided and the voluntary schemes the object kept in view is always the advantage to the community of maintaining in health the army of workers of all classes, the prevention rather than the cure of disease, and [illegible] the world and rearing of a race of [illegible]. In speaking of the hospitals, the Commission testifies to the great developments which have taken place in them since the early part of the last century, and points out that since then "the growth of operative surgery has increased the demand for hospital treatment, and in spite of frequent extensions of hospitals the demand is still in excess of the accommodation." The history of hospitals in connexion with poor-law infirmaries is traced through the time when the poor-law guardians had to send to the hospitals all cases needing special treatment and surgical operations, to the present day, while now the great difficulty the hospitals have to contend with is the elimination of those cases applying for admission to them which would more appropriately be treated in the workhouse infirmary. At present, it must be remembered that the hospitals stand between the sick poor and pauperism—the aid they give is the free gift of the richer to the poorer, and its acceptance brings with it no slur or disability. Increased usefulness and influence is suggested for the hospitals in the future when, if the central recommendation of the Commission is carried out, there will be a "Medical Assistance Committee" in every district, on which the voluntary hospitals will be represented, so that "overlapping" may be avoided, so that the help of the hospitals may be secured to those whose need is sorest, and so that their fullest possible effectiveness may be made certain. Meanwhile, they will continue their work with patience and energy, relieving pain and restoring the toiler to health, conscious that any change [illegible] them will in all probability be long [illegible] so with the knowledge that the work of restoring the poor to health in whatever class of institution it is being carried out is conducted in emulation of their example, under the direction of men trained in their schools.

The supporters also of the Metropolitan Hospital Sunday Fund in the past, as well as those who now first subscribe to it, will be aware that the work of organizing economically medical aid for the poor, the necessity for which the Commission dwells upon with such emphasis, will include the very services which the Fund, as a pioneer, has rendered already so far as its powers have permitted. It has distributed assistance systematically, after acquiring full information with regard to the means and conduct of each institution to which it has allotted the money subscribed by its contributors. It has not only preached economy and careful administration, but has insisted upon them; and those who have brought their offerings to it have had the certainty that they have contributed to a system which has typified method and order in the distribution of charity, promoting the generous relief of suffering without niggardliness, but also without waste.

The Promise of a more effective Ambulance Service.

The Report of the Poor Law Commission does not stand alone, however, as the result of an official inquiry into the needs of the poor in sickness made known during the past year. An investigation directly affecting the hospitals of London, with a view to making their work more effective, was ordered by the Home Secretary at the end of 1906, and was entrusted to a departmental committee composed of three members who were requested to inquire as to the provision made for dealing with cases of accident and sudden illness occurring in streets and public places in the metropolis. They were to express their views as to what improvements in ambulance provision were necessary or desirable, and as to how such improvements could best be brought about with due regard to efficiency and economy. With the details of the Committee's recommendations we are not here concerned, but we may note, as relevant to the case of the hospitals in any appeal for help, that it found itself obliged at an early stage to prosecute its inquiries far beyond the strict terms of the reference which has been set out above It soon became obvious that an ambulance service to be effective must bring to the hospitals cases of accidental injury and of ill[illegible] the limits of the County [illegible]ropolis" proper, and accord[illegible] of the wider area under [illegible]lon Police were considered and discussed It was urged also on the Committee that cases appealing for means to reach the hospitals quickly and safely were not confined to those accidents and onsets of illness which are constantly occurring in streets and public places The Committee decided that the service must be at the disposal of *those injured or suddenly taken ill in a* factory, at a railway station, or in a humble home, and of those lying ill in such places and surroundings as preclude the possibility of proper treatment and nursing These extensions of scope have introduced difficulties as to the proper authority under which any ambulance service should be placed, but they also made it abundantly manifest that the newly-perfected means of mechanical propulsion must be taken into consideration and that the "rapid ambulance" so desirable in the majority of cases would probably have to be summoned by a well organized system of telephonic communication Such a service for bringing accidents and illness to the hospitals speedily and efficiently by means of locomotion rapid enough to nullify the inconvenience of a *long journey would be quite obviously an immense* boon to the sufferers treated, but to provide it is beyond the powers of the hospitals themselves Its provision would have to include not merely the purchase of vehicles of a costly character, but also the housing and maintaining of them, and of the necessary staff of drivers and attendants, together, possibly, with the institution and upkeep of call boxes, and the making of arrangements for the use of public and private telephones according to need All this is outside the sphere of the hospitals, which will see with satisfaction the establishment of an Ambulance Service, but will see also that it will not lessen the strain upon their resources—it will increase it Cases which are now not brought to them because the distances to be traversed are too great and the means of transport are insufficient will arrive urgently demanding admission, with the result that the institutions which already have more to do than they can accomplish will be systematically "fed" with patients as if they had "asked for more" In the prospect, *therefore, of an* Ambulance Service worthy of London and of modern civilisation we see proof of public esteem for the good work done by the hospitals, the certainty that the suffering of the sick *and injured* will be lessened, and at the same time, one more reason why the Metropolitan

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund

Hospital Sunday Fund should retain and secure the hearty support of all.

The Children Act, 1908.

An important statute passed for the protection of children has recently come into force, which, although it cannot be said to affect the Hospitals directly, testifies indirectly to the desire of the nation to safeguard the health of the young and thereby to increase the usefulness of its citizens, and must also tend to increase the demand for hospital accommodation for children. In particular it makes the neglect punishable by law when a parent or other person legally liable to maintain a child shall fail to provide the child with adequate food, clothing, *medical aid* or lodging, or if being unable

otherwise to obtain these things he fails to take steps to procure them under the Acts relating to the relief of the poor. We all know the reluctance of the working classes (and of many who work but little) to have recourse to the guardians, and also the restrictions and conditions which attach to poor-law relief; and it is not d[illegible] which existed befor[illegible] a sick child is now [illegible]

enforced, the tendency will be to bring children more often to the hospital and to endeavour to obtain for them treatment as in-patients or as out-patients when there is any risk that the omission to do so may be visited with penalties. We have no wish to labour our point or to carry our argument further than it will lead us naturally and obviously. We maintain, however, that the direction of modern feeling as evinced in the inquiries of the Poor Law

Commission and of the Ambulance Committee, and in the Children Act which came into force at the beginning of last April, is towards increasing medical responsibility for the health of what we know as the "masses." In that responsibility the hospitals will have to bear their share, probably rather more than their fair share, and the Metropolitan Hospital Sunday Fund presses its demand that they should be enabled to bear the burden. None will grudge the gift who think of the suffering children of London. In health, their lot is not to be envied. In illness, or when accident befalls them, the hospital opens its doors to them as a haven in which they can find relief, and more than that can forget for a while the crowded street, their playground, and the reeking room, their only home. If all to whom the opportunity occurs to contribute to the Hospital Sunday Fund could only visit one or two hospital wards filled with children for half an hour before the plate or bag came before them, the resources of the Fund would be hugely raised.

Another reason for a Liberal Contribution.

Yet another reason may be added for the need for special effort in 1909 in order to keep the annual collection of the Metropolitan Hospital Sunday Fund at its usual high level. We are at peace with the world. It is now several years since the country had to bear the stress of the South African war and its accompanying expenditure of the national resources. Nevertheless, the recent years of peace which we have enjoyed have not been markedly years of prosperity or of "good trade." Liabilities affecting the nation must be met by those having charge of its finances, and methods of taxation necessary in the eyes of a Chancellor of the Exchequer do not always secure the cheerful acquiescence of those upon whom the burden is cast. It is often threatened by those who consider that they have been hardly treated by the imposition of fresh or increased taxes that their economies occasioned thereby must take in the first place the shape of diminished contributions to charity. We hope that as a matter of fact so ignoble a threat is but rarely carried out, and that such diminution of almsgiving does not take place save only when necessity absolutely compels it. We hope also that in all such cases gifts to the hospitals of London are the last to be withdrawn. Sometimes, however, charitable gifts must cease to flow from their accustomed sources for various reasons, and then the charity must put up with the loss unless others will come forward and make it good. We call upon all, therefore, in the current year to see that neither bad trade nor the course of taxation shall affect to its loss the Metropolitan Hospital Sunday Fund. Whatever the condition of England's commerce may be, the hospitals of London must carry on their business unflinchingly. Their commerce is one that brings them no profit in a financial sense, but they appeal to all to prevent them from carrying it on at a loss. They endeavour to frame their estimates for the financial year with

all the care and skill that they can command. Experience has taught them to be prudent; it has also taught them not to be over sanguine. They practise every economy that is consistent with the efficient discharge of their duty. If they suffer loss of income, if at the end of their financial year the balance is against them, it is because their revenue has fallen short of their expectations, and perhaps because some of those to whom they have looked for support have failed them. Such failure will be due, no doubt, to necessity and not to any lack of good will; but it has as its result a deficit instead of the modest degree of solvency for which they hoped. They impose no tax except that which the generosity of their friends will enforce. They levy no duty upon which they can insist. They can only appeal to all who "have" to assist in the name of charity in allaying the sufferings of those who "have not." From those who have health they crave aid on behalf of those whose health has failed, and who have been rendered helpless thereby; who have been struck down by physical injury or disease against which they have made no provision while in health. They ask it of those who have wealth, and of those who have that [illegible] the slender [illegible] om sickness [illegible] unless help [illegible] the part of the labourer and artisan, which will help to keep his family from want while he is in the hospital. Many a man, and very properly, makes an inroad upon his savings with this object in view, but let us remember that for many hundreds of thousands of our countrymen it is not possible to make such provision for contingencies as will safeguard them when serious illness or accident befalls. They belong to the class whose occupation renders them liable to accidental injury in a degree which their neighbours in other walks of life may scarcely realise. They live in homes and under conditions which in the public interest as well as in theirs we hope to see ameliorated; but at present, at all events, they so live that disease is likely to find in them but little resistance to its attack; and the remedies which science places in the hands of the community for serious physical conditions are of a costly nature, including suitable lodging and food, highly trained nursing, surgical and medical aid, costly drugs, and costly apparatus. No economies that even the better situated of the working classes are able to make, can enable them to meet such a demand upon their resources, and if in the hospitals they accept charity no blame can attach to them in their misfortunes. But if times become better let them remember to contribute their mite. Others who come to the hospitals are lower in the economic scale: men and women whose labour is fortuitous, and who in casual work, often of the roughest kind, are even more liable to injury and disease than the artisan or labourer in regular employment. It is for such as these, too, that the generosity of the public is craved on Hospital Sunday. The alms of the charitable, which given promiscuously may mean the provision of a few meals or the tiding over of a temporary crisis of a life of chronic mendicancy, have a different signification when they contribute to the building up of health of those who thus will at least have the chance of

1884. Including £4500 from the International Health Exhibition.

1885, 1886, 1887. Including three donations of £1000 each from Dr. James Wakley, Editor of THE LANCET.

1891. Including £5000 from the late Duke of Cleveland, &c.

1894. Including a legacy of £5000 (less duty) from the executors of the late Mr. W. J. Whitaker.

1895. Including £10,000 from Messrs. Barnato and friends; £3400 from the Stock Exchange; £1000 from Lord Iveagh; and £1000 from Mr. J. B. Robinson.

From 1891 to 1896 Sir Saville Crossley, Bart., P.C., M.P., gave an annual donation of £1000, and since has divided his contribution between this Fund and King Edward's Fund.

1897. Jubilee year. H.R.H. the Prince of Wales started a Special Fund for Hospitals.

1899. Including £10,000 from Mr. George Herring, and £1050 from Mr. J. Lane Denham.

1900. Including a further £10,000 from Mr. George Herring, £1090 from Mr. Thos. King, and "F. H" £1000.

1901. Including a further £10,000 from Mr. George Herring, and £4000 from Sir F. Cook, Bart, M.P.

1902. Including a further £11,575 from Mr. George Herring, and £1000 from Mr. Charles Morrison.

1903. Their Majesties the King and Queen, with most of the other Members of the Royal Family, attended at St Paul's Cathedral. [illegible] ing, and [illegible]

1906. Including a further £11,000 from Mr. George Herring and £3000 on account of the legacy bequeathed by Mr. Herbert Lloyd

1907. Including £30,000 from the late Mr. George Herring's estate, and a second instalment of £3000 on account of the bequest of the late Mr. Herbert Lloyd.

1908. Including £35,000 from the late Mr. George Herring's estate, and an instalment of £2000 on account of the bequest of the late M Herbert Lloyd.

helping themselves. Such gifts as these are surely worth a little self-denial, the loss of a transitory pleasure, or the abnegation of a luxury which once enjoyed will leave nothing behind worth possessing. The present season may be one at which the prospect of financial burdens presses heavily upon some who in the past have been able to treat them more lightly; but we urge upon all that it would be unworthy of them to allow the hospitals and the poor whom they relieve to suffer thereby. The reward of satisfaction in a good deed done without ostentation will be to those who give freely.

All can and should give.

The Metropolitan Hospital Sunday Fund is not only an organization for collecting the alms of the wealthy and well-to-do, who in places of worship in prosperous neighbourhoods have helped it before, and will, we feel confident, aid it again most generously: it is also essentially the opportunity for all to give in proportion to their means. There is a time honoured and possibly trite expression, which has been used sometimes in jest and sometimes in earnest until its origin and its inventor have alike been forgotton, if any one person can ever have originated it. A hackneyed phrase, however, may sometimes be justly and seriously applied, and if we now say with regard to the Metropolitan Hospital Sunday Fund "All contributions thankfully received," we do so with every hope that those who read will realise that it is addressed in all earnestness to themselves and to their neighbours without exception. The Fund welcomes the gifts of all, and distributes them justly and evenly so that they take their part in sustaining those great healing institutions which have set an example to the whole of the charitable world. There must be very few who attend religious worship on Hospital Sunday so poor that they cannot give their mite, perhaps in gratitude for that which the hospitals have done for themselves or for their friends or relatives. There can be few children who cannot bring contributions which will show that they too have learnt something of the duty of self-denial and of thought for others. We have said above that all should remember to give themselves, and to remind others, so that none may be able to plead ignorance or forgetfulness. We refer not only to those Londoners who on Hospital Sunday may not attend at any place of worship because they seek recreation or for other causes. London at this season is filled to overflowing with strangers to whom it extends a ready welcome; some are from foreign countries, and others from various parts of the British islands or from distant portions of the Empire. Some are here for business, others for pleasure; but whether they are here to make money or to spend it on their own enjoyment, they should be reminded of the hospitals of the metropolis whose doors stand open to all who need their aid, and who bestow that aid without taking account of birthplace or of "settlement," of nationality or of creed. They should not be allowed to forget that if the qualification for admission to the hospitals of London is that of physical suffering which the hospital can allay, combined with poverty, there is one cause and one only which may bring about the denial of help to those whose claim for assistance is beyond question. That cause is in three simple words: "want of money." Insolvency almost every hospital risks each year, relying upon the repetition of those kindly gifts which have helped it in the past, but beyond a certain point a hospital cannot go, and the work has to be sadly curtailed and kept within limits which can only be made wider by the generosity of the public.

To that public appeal is made once more in 1909 on behalf of the Metropolitan Hospital Sunday Fund.

Audited and found correct, this 26th day of November, 1908.

(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall-street, E.C.

*** *In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee), we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.*—ED. L.

Printed and Published by the REGISTERED PROPRIETORS of THE LANCET, at 423, Strand, W.C., and Nos. 1 and 2, Bedford-street, Strand, adjoining.

Association did not see its way to adopt some means by which a knowledge of the very important facts contained in the appeals could have been brought to the notice of the public. It has been urged as an objection that any attempt to sow broadcast such a knowledge of the early symptoms of cancer of the womb would cause an unnecessary and painful feeling of anxiety to a large number of women. We do not think, however, that such an objection should be allowed much weight. It would be far better that even a large number of women should seek medical assistance unnecessarily in the fear that they may have cancer, than that, as happens at the present time, a still larger number should delude themselves with the hope that the symptoms they are suffering from are of no importance. It would be well if the practice adopted by many foreign and American obstetricians of making a local examination of all their patients before ceasing attendance upon them after a confinement was more commonly carried out in this country. We know that the making of such examinations, the immediate utility of which is not apparent, is a matter of much difficulty, and the adoption of any practice which would in the least tend to lessen the feeling of modesty would be most deplorable; but at the same time the price which many unfortunate women in consequence are compelled to pay is a very heavy one. Their condition is not realised until too late. The recognition of the very earliest signs of cancer of the neck of the uterus is, in particular, of the utmost importance because of the anatomical relations of this portion of the uterus. In the most favourable circumstances, and by the most extensive operation which it is possible to practise, the amount of healthy tissue beyond the limits of any growth in this region which can be removed is necessarily limited. The very close anatomical relations which exist between the cervix uteri and the bladder and ureters render a sufficiently adequate removal of even an early growth and the tissues surrounding it in this position a matter of much difficulty. Indeed, it might be said that one of the causes of the high death-rate from cancer of the womb in women is the anatomical relations of the ureters in the intrapelvic portion of their course.

One of the most important errors prejudicing the lay view of cancer is that the disease cannot be present without the presence of a great deal of pain. When we recall the extreme anguish which many sufferers have to endure in the later stages of most of the varieties of malignant growths the mistake is not an unnatural one. In this connexion midwives and nurses can do much to instruct their patients as to the truth. They may teach them the important facts, rightly laid great stress on in the portion of the appeal addressed to nurses, that "cancer may occur at any age and in a woman who looks quite well and who may have no pain, no wasting, no foul discharge, and no profuse bleeding." The snipping out of a portion of the tissues of the cervix for microscopical examination is so simple and painless a procedure that we may hope the issue of the appeals will lead to this being carried out in all doubtful cases of enlargement or disease of the cervix uteri much more frequently than is at present the case. There is no difficulty in these days in obtaining an expert pathological opinion about such a piece of tissue, and in all cases of doubt it is certainly wisest to err upon the safe side and to have the diseased tissues widely and thoroughly removed. Hitherto the ultimate results of operations undertaken for the removal of cancerous growths of the uterus have been so uniformly disappointing that many people have lost all faith in the possibility of cure by operation. This is mainly because operative procedure usually comes too late. Patients and the public should realise the fact that the outlook in cancer in the early stages, if properly removed, is by no means so hopeless as it was, and the total number of patients cured is increasing day by day. We trust sincerely that the appeals issued by the British Medical Association may bear good fruit; and we hope that the committee which has drawn up the appeal will not consider its labours at an end, but that it will continue the work with the object of spreading a knowledge amongst women themselves of the important facts which they have promulgated. Both the medical man and the nurse are powerless unless the patient will confide in them, and in many instances the dread of cancer leads the unfortunate patient to hide her symptoms until it is too late for the medical attendant, when she does seek his help, to be of any service.

Lord Lister and the Antiseptic Method.

IN another page of this issue we have reviewed the collected works of Lord LISTER, which have been published as a memorial of his eightieth birthday. Modern surgery dates from the introduction into practice of the principles laid down by LISTER more than 40 years ago. Before that time surgery was chiefly characterised by its uncertainty. An operation might be performed with the greatest care, the design of the operation and its performance may have been of the highest type, but no one, not even the greatest surgeon of the age, could say with any approach to certainty that recovery was likely to follow. Primary hæmorrhage had ceased to be the bugbear of surgeons which it had been for centuries, for the ligature and torsion had succeeded almost completely in putting an end to the fear of hæmorrhage at the time of the operation; but only too often, some ten days or so after the operation, secondary hæmorrhage, as it was called, burst forth, and this was by far more troublesome and dangerous than primary hæmorrhage, for it might occur at any moment—in the middle of the night, as well as during the day, and the pouring out of the blood in a full stream might pass unnoticed by everyone, even by the patient himself, until so much blood had been lost that recovery was impossible. Even when the bleeding was seen it was no easy matter to restrain it, for it might come from the depths of a wound which had almost healed. Let us suppose, however, that the patient had successfully passed by the danger of secondary hæmorrhage, was the wound likely to heal without any other unfavourable manifestation? By no means: in any circumstances various septic complications were not unlikely to follow. Erysipelas was not a rare visitant to a healing wound and in nearly every case free suppuration occurred, while in hospital practice the most striking manifestations of sepsis were to be generally seen.

Pyæmia and septicæmia frequently occurred in hospitals and caused many deaths, but even more noticeable was the disease to which the conditions of its occurrence gave the name of "hospital gangrene." This was rarely met with out of hospitals, but in hospitals it was fairly frequently seen. Grey points of slough appeared on a wound and spread rapidly until the whole surface was affected, and the surrounding skin, of a dull red, was soon involved in the sloughing process.

Little was known of the causes of these severe septic complications, but theories were devised to explain the facts. The mere presence of pus was held to require no explanation; suppuration was the natural way, or one of the natural ways, in which a wound healed, and so long as the pus was discharged freely, and it was of the usual tint and odour, it was looked upon as beneficial rather than otherwise, and the name "laudable pus" which was applied to it conveyed this idea. To a certain extent there was a small foundation for this favourable view of free suppuration, for it betokened the complete formation of granulations which offer a very thorough opposition to the absorption of septic organisms or their products. Distinctly septic manifestations were at this time in part ascribed to the influence of the atmosphere or to winds from certain quarters, but it became recognised that overcrowding of wards frequently preceded the appearance of the more severe complications, and that when the percentage of open wounds in a ward was high the risk of the occurrence of pyæmia or hospital gangrene was especially great. Sometimes one or both of these diseases invaded a particular ward and remained in it in spite of all precautions, until it was found necessary to close the ward. Indeed, so prevalent were these and similar septic affections in hospitals that a special word, "hospitalism," was invented to designate, if not to explain, this unfortunate tendency to septic processes observable in hospital. One eminent surgeon was so convinced that the cause of these complications was connected with the wards that he suggested that a hospital should no longer be built of such permanent materials as brick or stone, but that it should be made of wood, so that when it had lasted some few years it could be pulled down and another wooden hospital raised in its stead, which, for a time at least, would be free from these severe septic manifestations.

The methods of dressing wounds which prevailed were calculated to spread infection. Sponges were used for bathing wounds and ulcers, and though they were washed in water after being employed for one patient they were carried straight to the patient in the next bed. Instruments also used for dressing wounds were only washed in water before being employed on the next patient, so that probes were frequent mediums to convey infection into the deeper parts of wounds. In operations, too, the conditions which prevailed must appear strange to the modern student of medicine. Hardly any cleansing of the patient's skin or the hands of the surgeon and his assistants occurred. The instruments were washed after use in one case before being employed for another, but the washing was not thorough. The ligatures employed were of silk which had been well waxed so as to make them hold more firmly, and a favourite and convenient receptacle for the ligatures during an operation was the button-hole of the coat of the house surgeon, whence they were taken as they were required. When drainage was free suppuration became fully established in three or four days, and the wound granulated from the bottom. Occasionally it happened that union by first intention occurred, but this was not encouraged, for the ligatures had been left long and had been brought out at one end of the wound, and till these separated healing tended rather to the accumulation of pus; while if it happened that no ligatures had been employed primary union of the skin was very liable to be accompanied by suppuration and the accumulation of pus in the deeper parts.

The results obtained after injury or operation naturally varied greatly with different surgeons and in different sanitary conditions, and on the whole it might be said that the results of operations in private practice were better than those obtained in most hospitals. After major amputations the mortality was very high, for it varied from 30 to 50 per cent. In some statistics of Nussbaum's cases it is stated that of 17 cases of amputation 11 died from pyæmia. This was exceptionally severe, but it is certain that fatal results from septic processes were very common. It is not, however, merely from the mortality that a just comparison may be made between the pre-Listerian days and the present Even in the cases that recovered the difference was enormous. After an operation the old-time patient suffered much pain for the first three or four days, the edges of the wound became swollen and tender, and his sleep was disturbed; this discomfort became slightly mitigated on the full establishment of suppuration. Then came the risk of secondary infections, pyæmia, septicæmia, and hospital gangrene which we have already mentioned, while erysipelas and tetanus were also frequent complications, and if the patient escaped or survived an attack of one or more of these it often required many weeks for recovery. In cases of compound fracture necrosis frequently followed, and the process of separation of the necrosed portions of bone might occupy months. It is true that in some special cases good results were obtained, for instance, Keith's cases of ovariotomy gave a mortality wonderfully low when we consider the date at which the operations were done, but Keith used cleanliness in everything connected with the operation, and to this must be ascribed his excellent results. Putting aside instances such as these which were utterly exceptional, we must recognise that before Lister made the attempt to prevent sepsis in cases of compound fracture a large proportion of cases of injury and of operation proved fatal from septic disease, and a very large proportion suffered greatly from septic processes. From all this Lister has delivered us.

The most extraordinary ideas prevail, not only among the public but among the recent recruits to medical ranks, as to what Lister exactly did. By some his achievement is supposed to have been the discovery of carbolic acid or its application to surgery, whereas carbolic acid, though unused then in the British Isles for surgical purposes, had been used abroad. Others imagine that his method merely consists in using carbolic acid in wounds. Those who think thus of Listerism have not the faintest idea of the real work which LISTER did The antiseptic method depends on a principle, viz, that for the perfect healing of a wound it should be free from germs, and this principle depended on a theory that the cause of decomposition in a wound is the presence of germs The words septic and antiseptic were no creations of LISTER's, as many seem to imagine, they date back at least 200 years before his time, the meaning of septic was fermentative and decomposing, and an antiseptic was any substance that could prevent fermentation or decomposition Salt, wine, vinegar, and cold were all recognised generations ago as possessing antiseptic powers, and LISTER's theory, based, as he freely acknowledged, on PASTEUR's researches, was that it was not the entrance of air into a wound, but the entrance of germs with the air, that led to decomposition and other septic processes, and he pointed to the difference in the results of a simple and a compound fracture as illustrative of the nature of the origin of septic processes His first cases treated antiseptically were compound fractures, and the problem was, how can this wound be made and kept free from germs? As *some hours had usually elapsed between the infliction of* the injury and its being seen by him, LISTER recognised that germs must have already contaminated the wound and he set himself to destroy all the organisms which had already gained entrance To this end he wiped out the recesses of the wound with liquid carbolic acid and covered the opening with a piece of lint dipped in the carbolic acid, and recovery *ensued without any suppuration* The event had served to prove the truth of the theory The details of the method mattered nothing in themselves so long as they led to the same result—the destruction and exclusion of germs The details were varied from time to time, carbolic putty was invented, then carbolic lac plaster was devised, sheet tin dressings were applied, but in each and every case the principle was the same Gauze gradually made its appearance and the spray was instituted, but all this was done with regard to the same principle—the exclusion of germs from the wound. Further changes ensued; medicated cotton wool and then simply sterile cotton-wool was employed as an outer dressing The spray was discontinued, but without any change of principle Corrosive sublimate dressings were *introduced, and these were replaced by dressings of the* double salt sal alembroth, and later still the double cyanide of mercury and zinc was recommended as being superior to the others Through all these changes one unceasing purpose runs—to prevent the access of pathogenic germs to the interior of a wound whether caused by injury or made by the surgeon in the course of an operation

When in process of time aseptic surgery arose it was nothing more than the elaboration of the same principle The employment of heat for sterilisation of dressings and instruments was no new thing, for in many of his earlier researches LISTER had used heat to sterilise apparatus he was employing Aseptic surgery stands in no antithesis to antiseptic surgery It is merely a simplification of the original form, and simplification has been proceeding from the very inception of the antiseptic method. LISTER himself early recognised that the application of liquid carbolic acid to the interior of a wound caused much unnecessary exudation which required special arrangements for its removal, and it was not very long before he replaced the liquid carbolic acid by a 5 per cent solution It would be a mistake to imagine that even in the aseptic method we have reached finality, though we cannot at present see the direction that any improvement can take It is, however, certain that from LISTER's first case in 1865 to the present time the evolutionary process has been continuous The benefits conferred by LISTER's invention are, moreover, not confined to the improvement of the operations practised at the time of the introduction of antiseptic surgery Great though that change has been, that is to say from almost unlimited sepsis after operation to almost certain asepsis with rapid healing, *yet in another direction the change has been greater still* The field of operation has been wonderfully widened. Regions of the body that were left untouched, and were held to be untouchable by the surgeon, are now dealt with as a matter of daily routine, and the beneficial results are commensurate with the enlargement of the scope of surgical activity—in other words, the gain to humanity is incalculable.

The reception accorded to LISTER's work by his own profession was hardly what might have been expected The mistake of imagining that he had merely suggested a new lotion for dressing wounds was commonly made He had put forward a principle, and it was *imagined that he had merely introduced a drug* Carbolic acid was expected *to do all that the principle* promised, and as in its use the principle was frequently disregarded, disappointment naturally followed Even some of those who appreciated to an extent that the complete destruction of bacteria in the wound and their exclusion from the wound were both to be obtained seem to have thought that the more carbolic acid that was applied the better the result would be LISTER laid down most carefully the principle that the swabbing or washing out of the wound was only to be done once and for all, and that thenceforth the less the carbolic acid came in contact with the wound the better, but his teaching was regularly violated with the best of motives Abroad, as at home, the acceptance of the antiseptic method was slow, but every *surgeon who tried it thoroughly continued to employ it, and* the effect was amazing In VOLKMANN's wards in 1871 the deaths from pyæmia and septicæmia were so numerous that he made up his mind to close the hospital altogether for a time, but before doing this he resolved to try the antiseptic method for a few weeks, and the results were very satisfactory This was typical of what gradually took place everywhere, but as a rule the younger surgeons were more ready to adopt the methods of aseptic surgery, and for some years after the laying down of the right principles there were some surgeons who while they practised aseptic surgery as they understood it, did not look upon a freely suppurating wound as a failure so long as the grosser forms of sepsis were absent These times, however, have now passed away.

It should be of interest for us to see, without aiming to detract in the least from LISTER's originality in the invention of antiseptic surgery, if there was anything in the circumstances of his life which predisposed him to make the discovery. We find at once that he had a wider scientific training than most other surgeons of his time. His father, J. J. LISTER, had devoted a very large amount of attention to scientific matters, and especially to improvements in the achromatic microscope, so that LISTER had grown up in a scientific environment, and at an early age had the use of as good a microscope as was then procurable. The bent thus received led him to devote much attention while at University College, London, to the study of physiology under SHARPEY and of chemistry under GRAHAM, two men who stood at the very summit of their respective sciences. The knowledge so obtained stood him in good stead later and helped him not only in his physiological and bacteriological researches but also in arranging the practical details of his methods. It was a great advantage to him also that he had much experience of surgery both in University College Hospital, London, and in the Royal Infirmary, Edinburgh, and so observed and practised very different methods of treatment. This large opportunity enabled him to appreciate that the untoward results of operations were not the fault of any individual surgeon or of any particular surgical method but of the whole system; and when he found that as surgeon at Glasgow he was unable by all the means then in his power to stem the current of sepsis he was led to apply the bacteriological knowledge he had gained to the attempt to solve the problem of sepsis. Natural bias, early training, good masters, a wide field of observation, enormous industry and genius—these are the things which went to the discovery of the antiseptic methods.

Annotations.

"Ne quid nimis."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

WE publish this week our usual Special Supplement in support of the Metropolitan Hospital Sunday Fund. The interests of this Fund have since its inception appealed particularly to THE LANCET, and we hope that the appeal from the pulpits to be made on Sunday, June 13th, will meet with a hearty response.

ILLNESS IN THE ROYAL FAMILY OF ITALY.

IN supplement to the details given in our correspondence as to the health of the Queen-Mother an Italian contributor writes:—"Her Majesty still suffers from pain, neuralgic and muscular, at the cervical vertebræ; pain severe enough to make movement of the neck all but impossible. In consultation, it is understood that Dr. Baccelli inferred a tetanic indication, in abatement of which hypodermic injections of phenic acid have been practised, in addition to those of morphine. The continued suffering and the loss of sleep have reduced the Queen-Mother's strength considerably, and since May 21st a physician has sat up with her Majesty at night, relieving a colleague in attendance during the day. In professional circles it is surmised that Her Majesty has subjected her system to excessive strain by the long and rapid journeys she has been accustomed to take in her automobile. That mode of progression, indeed, is so much in favour with Her Majesty that she had contemplated a tour through Japan in the vehicle—a project which the present illness has forced her to abandon. At the Villa Margherita the inquiries as to the health of its august inmate are incessant, and the visitors' book receives many signatures daily from members of the *Corps Diplomatique* and the patrician world. As soon as the conditions permit, the Queen-Mother will be removed from Rome to a more opportune summer *villeggiatura*. As I write, I am informed that H.R.H. the Duke of Aosta is lying ill at the Palace of the Quirinal from bronchial catarrh, and that his consort, the Duchess Elena, has arrived to assist at his bedside. Fortunately, the temperature, which at first exceeded 39° C., is now nearly normal, and according to to-day's bulletin the conditions are those of 'full defervescence.'"

THE MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held at Bristol on Thursday, May 27th, when the annual report of the council and the statement of accounts were received. The annual report demonstrates once again in an unmistakeable manner the advantages which are obtainable from being a member of one of the defence societies. Not only does it convey protection from an attack by unscrupulous persons upon the member's professional character, but he can at any time seek the advice of the executive upon all matters which involve professional principle, and if he be wise he will not hesitate to seek such advice as soon as he finds himself in a difficulty or sees one approaching in the distance. A useful warning is once more contained in the report which members will do well to heed—namely, that many an action has been imperilled by unwise procedure adopted by members before seeking skilled advice; such instances are still constantly met with, but are becoming less numerous since this caution has been drawn attention to. Many members have fallen into this error by not desiring to trouble the Union in what seems to be a small matter, but it is very difficult to estimate the manifold possibilities of an apparently simple case, therefore advice should be sought before any amateur efforts are made to attempt to warn off legal complications. An important new step has been taken by the council of the Union and one which will enhance the value of membership. In the last report the matter of indemnity against adverse verdicts, where members by such are directed to pay the costs and damages, was considered. The subject has since been very carefully discussed both at executive and council meetings, and it has been decided to offer an insurance against such events. The details of the arrangements are stated in the report. Briefly stated they are as follows. Where an adverse verdict be given against a member who is thus insured, the taxed costs of plaintiffs and "damages ordered" up to the limit of £2000 or £2500, as the case may be, will be paid by the Yorkshire Insurance Company. The annual premium to be paid by insurers for the limit of £2000 in any one action will be 7*s.* 6*d.*, and for the limit of £2500 will be 9*s.* Also "where a settlement is arrived at with the consent of the Yorkshire Company 'out of court' or 'in court,' after proceedings have commenced, the costs, if any, of the plaintiff, and the sum agreed to in settlement, be defrayed by the Yorkshire Company." These arrangements seem to us to be business-like and the members of the Union will be well advised to take advantage of them. The report of the solicitor (Mr. W. E. Hempson) is, as usual, of a most interesting character. Numerous cases are cited which were referred to him to deal with, and during the year 128 such cases were actually carried through, disposed of, and completed. Of these, 40 were libel and slander actions taken or defended on behalf of members; 25 were actions in which damages were claimed for malpraxis; seven were cases relative to the prosecution of unqualified persons and the suppression of unauthorised practice; while the remaining 56 had relation to matters generally affecting the interest of the members or the profession, in which the support or intervention of the Union was sought. During the year two cases were compromised at the express request of the members involved, and in one case the Union was not successful in obtaining a verdict on behalf of the member concerned. With these exceptions, each and every matter referred to and undertaken by the Union was brought to a successful issue. The financial condition of the Union is highly satisfactory, and we offer our congratulations to the members of the council of the Union, to the solicitor, and to the general secretary (Dr. A. G. Bateman) on a valuable and satisfactory year's work.

WEATHER FORECASTING.

THE Director of the Meteorological Office has just issued an intimation that he is prepared to furnish special weather forecasts for the four months June to September, 1909. These forecasts are principally intended to further agricultural operations but as medical practitioners may frequently desire to have trustworthy information of this kind, either for personal use or for the benefit of a convalescent patient who may contemplate a journey away from home, we append some of the details from the circular. Particulars of the scheme, with forms for application, may be obtained from the Director, Meteorological Office, 63, Victoria-street, London, S.W. The official number of the circular is 052. Forecasts for the probable weather of the ensuing 24 hours, beginning at midnight on the day of issue, will be despatched, each week-day from the office by telegraph at 2.30 P.M. The forecast will be 12 words in length and the address will be additional. The cost of each forecast will therefore be 6*d.*, in addition to ½*d.* for every word of address. The office is also prepared to send notification by telegram whenever the conditions appear favourable for a continued spell of fine weather. The notification will take the form of a forecast covering a period of not less than two days following the date of issue. Those who wish this notification to be sent must deposit a fee of 2*s.* 6*d.*, which includes the cost of the telegram. Recipients who are willing to coöperate in the matter will be supplied with forms on which they can record the actual weather experienced for the purpose of comparing the forecast with the actual weather.

VACCINE THERAPY.

IN another column we publish a paper read before the Therapeutical and Pharmacological Section of the Royal Society of Medicine by Dr. W. Hale White and Dr J. W. Eyre on the results of a year's use of vaccines in general medicine. It is considered by many observers, and we believe rightly so, that vaccine therapy will be employed in the future far more than has hitherto been the case. Satisfactory results have been reported in numerous conditions of microbic origin. The vaccines which probably have produced the most favourable consequences have been those obtained from the gonococcus and the bacillus coli communis. Dr. Hale White and Dr. Eyre record some interesting cases in which these vaccines were employed. One case was particularly striking. A man arrived from India in a very debilitated condition and was expectorating large quantities of blood and pus. Operation was not considered advisable on account of his extreme weakness and a vaccine was prepared. The result was excellent, complete recovery ensuing. With further experience it will probably be possible to extend the use of vaccines to those conditions in which, as yet, good response on the part of the patient has not followed. In croupous pneumonia, for example, numerous attempts have been made to employ vaccine therapy, but up to the present the results have been by no means all that could be desired. One of the drawbacks to this form of treatment is the time that is required to prepare a vaccine, but as the danger in pneumonia does not arise until a late period of the disease, this difficulty is not so formidable as in some other conditions. Dr. Hale White and Dr. Eyre excluded cases treated with tuberculin, giving as an explanation of this omission the length of time that must elapse before any conclusions can be arrived at. Results which have been obtained by various investigators, however, suggest a line of treatment in pulmonary and other forms of tuberculosis which is of great promise. With regard to the pulmonary form, tuberculin may be employed as an addition to the sanatorium treatment, especially in those patients who are unable to undertake but little exercise on account of constantly recurring auto-inoculations.

THE ROYAL COMMISSION ON VIVISECTION.

A LETTER signed by various members of the Research Defence Society has been sent to the Home Secretary. The letter states that—

> [illegible]

The letter has been signed by the Earl of Cromer, President of the Research Defence Society; the Hon. Sydney Holland, chairman of committee; the Duke of Abercorn, Lord Avebury, Lady Bliss, Lord Robert Cecil, Lord Cheylesmore, Sir Savile Crossley, the Hon. Walter Guinness, Sir Edwin Ray Lankester, Sir Frank Lascelles, Mr. Frederick Macmillan, the Earl of Malmesbury, Sir Patrick Manson, the Duke of Montrose, the Dean of St. Patrick's, Lord Rothschild, Mrs. Scharlieb, Professor E. H. Starling, Sir Reginald Talbot, Sir Frederick Treves, the Duke of Wellington, and the Bishop of Winchester. We are glad to see that the Research Defence Society has taken this step.

THE ILLUMINATING ENGINEERING SOCIETY.

A SOCIETY has recently been formed under the above designation. An executive committee has been appointed and has drafted its constitution and rules. A similar society has for some time been in existence in the United States and has met with great success. The object in view is to bring into intimate relationship all those who are in any way interested in the subject of artificial illumination. For too long a period this question has been entirely in the hands of technical experts, whose purview is limited and inadequately controlled. The aim of the engineer, whatever his medium—electricity, gas, oil, and so on—has been to obtain the maximum efficiency—that is, maximum illumination at minimum cost. The distribution of the sources of light has been controlled by the architect, who is perhaps unduly swayed by convenience and artistic considerations. Both he and the engineer have paid relatively little attention to the physiological problems involved. Always important, these have become still more so with the advance of the art of illumination. The introduction of new inventions, such as the metallic filament lamp, has led to the use of light extremely rich in ultra-violet rays. It is well known that these rays are deleterious to vision, and it has become imperative that some supervision shall be exercised over the artificial illuminants in general use. The object of the Illuminating Engineering Society is to bring together all the branches of the illuminating engineering profession, as well as architects, ophthalmologists, and physiologists, so that the problems may be fully discussed without any commercial bias and with the aim of the highest good for the greatest number only in mind. If the society maintains this lofty ideal it will deserve well of the medical profession and should receive its warm support. Further information can be obtained from Mr. L. Gaster, editor of the *Illuminating Engineer*, 32, Victoria-street, London, S.W.

A PROPOSED MEMORIAL TO THE LATE DR. J. J. RIDGE.

THE cause of total abstinence never had a stronger or more efficient champion than the late Dr. John James Ridge, of whose life we published an account in THE LANCET of June 13th, 1908 (p. 1729). No one who read that record of his character and achievements can wonder that a body of his friends have decided to perpetuate his memory in Enfield, the town of which he was medical officer of health for 27 years. We need not repeat at length the claims on which the appeal now in circulation on this behalf rests, but we will remind our readers that Dr. Ridge was a man of whom any profession might well have been proud. Before he came of age he had graduated in arts, science, and in medicine, besides gaining a university scholarship and gold medal in surgery at the University of London. Subsequently he took his M.D. degree twice over, in medicine and State medicine, and in both these branches of practice he did valuable work for the community. But the labour of his lifetime was above all devoted to the cause of total abstinence, which he was especially anxious to see rooted firmly in his own profession. He was the founder and the secretary of the British Medical Temperance Association from 1874 until he died; he formed half of the original staff of the London Temperance Hospital, of which he was a visiting physician for 25 years; he was first President of the International Union of Medical Abstainers, and for many years editor of the *Medical Temperance Review*. The first appeal for funds to provide a suitable memorial to Dr. Ridge was made at a recent public meeting at Enfield, when it was proposed, if the response should be sufficient, to erect a granite memorial in Enfield and to found a Ridge Convalescent Fund for the benefit of patients of the Enfield Cottage Hospital, of which Dr. Ridge was the founder. We believe we have only to make these proposals widely known amongst the medical profession to obtain some response from his admirers, and we are asked to state that donations may be made to the honorary treasurer, Dr. Howard Distin, Holtwhite House, Enfield.

THE RADIOGRAPHY OF CERTAIN DYSTROPHIC DISEASES OF BONE.

EVERY medical visitor to Paris knows the Musée Dupuytren with its wonderful osteological collection. The opportunity has been afforded M. Legros and M. Léri of making a systematised x-ray examination of the numerous specimens of bone disease there preserved, and their first communication on the subject is published in the latest number of the *Nouvelle Iconographie de la Salpêtrière*. It is devoted to a consideration of four morbid conditions of the bones between which there exist certain clinical resemblances; on the one hand, Paget's disease (osteitis deformans) and delayed hereditary syphilis with osseous manifestations, two diseases which in the opinion of some observers are similar, if not identical; on the other, osteomalacia and rickets, conditions producing bony deformities sometimes more or less analogous to those of the other two mentioned above, as well as presenting certain features in common. The radiographic picture of Paget's disease is characteristic and curious. In addition to condensation or rarefaction of the outer shell of compact tissue the photographs show an appearance compared by the writers to a tangled skein of the finest wool; delicate osseous threads pass to and fro in all directions, either limited to the centre of the bone or ramifying from one end to the other, sometimes reticular, sometimes anastomosing, sometimes arranged in whorls. Where the epiphyses are invaded they lose their normal contours, and in the pictures the ends of the bone look "woolly." This appearance is pathognomonic of Paget's disease. In the osseous manifestations of delayed hereditary syphilis, on the other hand, there is found a solid or almost solid mass of new-formed bone in concentric layers, while the architecture of the rest of the bone is regular and normal. The radiographic appearances of osteomalacia are also very curious The outer layer is intact throughout most of the diaphysis, but the epiphyses are thinned and scarcely recognisable; the whole extent of the central part of the bone is transparent, and is crossed at wide intervals by dense opaque partitions, running transversely or obliquely, so that large clear irregular alveoli are formed, as much as three or five centimetres in diameter. This appearance is pathognomonic of osteomalacia. In rickets, notwithstanding the curvatures, the normal disposition of the bony layers is more or less preserved; on the concavities the compact bone is thickened, and in the centre a degree of rarefying osteitis is found, but there are no large alveoli, and no rarefaction of the epiphyses.

DISEASED ALIENS: THE UNITED STATES AND CANADA.

REFERENCE was made in THE LANCET recently to the passage of alien immigrants through Liverpool on their way to the United States and to Canada, and to the frauds practised upon them. The law of the countries mentioned is being strictly enforced in order to prevent the importation of undesirable citizens, among whom are those suffering from disease, and the suffering are easily robbed under false promises either that they shall be cured or that they shall be smuggled into the country for which they are destined. Two migrants recently made their appearance at the Guildhall police court charged under the provisions of the Poor-law, and their stories, extracted from them with difficulty by interpreters, although containing no imputation of fraud against anyone, illustrate the way in which England is used as a clearing house. The first man was apparently an Armenian from Kharput, in dominions ruled by the Sultan of Turkey. He had found his way thence about three months ago to Liverpool, where he paid £6 for a passage to New York. There the medical authorities refused to let him land and he was shipped on to Canada He succeeded in getting ashore in Canada, but went no further than a hospital, where he was detained for a few days until he could be re-consigned to Europe. The ticket given him for this purpose seems to have been for a second-class passage to London *viâ* Rotterdam, and he made use of it as long as it would carry him, for he was found practically penniless, hungry, and quite incapable of making himself understood at Holborn Viaduct Station in company with the person charged with him. The second man seems to have met the first towards the end of his journey, for he travelled direct from New York to Rotterdam without visiting Canada. He had been shipped to America *viâ* Naples and Liverpool from Tripoli in Syria, but he too had been prevented from landing by the New York medical authorities. There was some difficulty in extracting the above story for the benefit of Alderman Howse at the Guildhall, but the workhouse authorities had succeeded at length in finding interpreters, and the magistrate had no difficulty in certifying the men to be aliens. Their story will have been communicated to the Home Office, which will deal with them, and meanwhile they remain in prison. After all, they do not deserve very much pity, as they must be deemed to have made long experimental journeys for which they had no justification, and if they commenced them at their own expense they will finish them at considerable loss to others, and more particularly to this country. It is difficult to argue that persons of their class, whom New York and Quebec are able to reject with promptitude, ought to be accepted without question in the ports of London or Liverpool, or that England is to be congratulated upon the policy at present pursued by her in such cases. It can hardly be suggested that it is right either to encourage diseased wastrels to remain here, or to help them to spend their money on fruitless travel to countries better able to take care of themselves than we are.

"MATRIARCHY."

THE contention of many excellent people that social laws are "man-made" and therefore press unduly upon women would at least seem to require some qualification from the point of view of the evolution of the human race. Marriage, for example, can scarcely be said to have existed among very primitive communities, and its institution may be due to women. Bachofen, contrary to many serious thinkers, believes that in the earliest times promiscuity was the rule, but "after a while the women, shocked and scandalised by such a state of things, revolted against it, and established a system of marriage with female supremacy, the husband being subject to the wife, property and descent being considered to go in the female line, and women enjoying the principal share of political power." At least as many people believe the converse—viz., that marriage was the man's way of keeping possession of his chattel, but if we accept the theory of Bachofen and his school, we reach the period of matriarchy, of which many relics still exist among civilised and uncivilised races. Speaking of matriarchy, Mr. Gomme, in "Folk-lore as a Historical Science," says that among many primitive peoples kinship with the father is purposely neglected as a social factor. Among the Khasia people in the hills of Assam the husband is only an occasional visitor in his wife's house, where "he seems merely entertained to continue the family to which his wife belongs." Among the Syntengs and the people of Maoshai the husband only visits his wife in his mother-in-law's house. In Jowai he is only a visitor after dark, the fact being that, according to Major Gurdon, among these people "the man is nobody ...... if he be a husband he is looked upon merely as *u shong kha*, a begetter." Among birds and fishes occur numerous instances of what for want of a better term we may call matriarchy. Thus the late Mr. Bartlett of the Zoological Gardens informed Charles Darwin that it was certainly the male ostrich alone who sat on the eggs and took care of the young, while the female during the breeding season became extremely pugnacious. Darwin further cites a description of the female of one of the emus, who is larger than the male and altogether fiercer. "The male has a slenderer frame and is more docile, with no voice beyond a suppressed hiss when angry, or a croak." He not only sits on the eggs, but defends the young at every turn from the angry female, which is bent on destroying them. A similar state of things is said to exist among certain Indian quails, the females of which are larger than the males, and among certain nest-building fishes, the males of which do all the work, and afterwards take exclusive charge of the young. So far as mankind is concerned matriarchy is a phase occurring early in the evolution of the races, and humanity apparently has not found a matriarchal system expedient to its development as the system has not survived in any race of the slightest consequence in civilised history; but this must not be made too much of as an argument, for a scheme of things may be of no great value to a primitive folk and yet be very serviceable to more highly developed communities.

A NEGLECTED SIGN IN OBSCURE ABDOMINAL DISEASE: "THE RECTAL SHELF."

AMONG the more obscure abdominal diseases are malignant disease of the various organs and certain forms of localised peritonitis. The importance of early diagnosis in the former is obvious. In the *Albany Medical Annals* for May Dr. George Blumer has called attention to a valuable sign, which he terms "the rectal shelf." Though not new it has been strangely neglected by writers on abdominal disease. In 1895 H. Strauss, the German gastrologist, stated that in some operations for cancer of the stomach he found metastases "in the liver, retroperitoneal tissue, and in Douglas's pouch, a situation which on account of its explorability merits more frequent examination." Four years later he said that in some cases he found the early and only metastasis in Douglas's pouch, and that in two cases this was the point which decided the diagnosis between gastric ulcer and cancer. Orth in the sixth edition of his "Diagnostik" states that in tuberculosis and carcinoma of the peritoneum, especially of the disseminated form, while there may be no growths in the neighbourhood of the pelvis, there occurs as a rule between the rectum and bladder a metastasis sufficient to cause pressure due to implantation of infective material in the most dependent part of the peritoneal cavity. As a result there is often a circumscribed fibrous inflammation. From coalescence of nodules a board-like inflammation of serous and subserous tissues may result and involve the rectum, and even penetrate its wall and give rise to the diagnosis of rectal cancer. Chiari states that such metastases are moderately frequent in gastric cancer. This sign did not escape some of the older writers. Thus, in 1835, Sym of Edinburgh described a case of tuberculous peritonitis (verified by necropsy) in which the medical attendant found a tumour in the anterior wall of the rectum during life that prevented the administration of enemata.[1] Similar observations in connexion with operations for cancer of the stomach have been made by Griffon and Nattan-Larrier,[2] and by Payr.[3] Kelling states that in every case of suspected carcinoma of the stomach "I examine the patient per rectum for glands in Douglas's pouch and for rectal carcinoma." Dr. Blumer describes the condition found on rectal examination as follows. The lower part of the bowel is usually normal, and not until the prostate is passed is any abnormality usually detected. In some cases just above the prostate, in others at the limit of palpability, two to four centimetres above, the finger, passed along the anterior rectal wall, impinges on a shelf of almost cartilaginous hardness which projects into the rectal cavity. In some cases further palpation shows that the whole rectum is involved in an annular zone of infiltration more marked anteriorly and tapering off towards the posterior wall. This condition is termed by Schnitzler "signet-ring stricture." In such cases the infiltration is no longer confined to Douglas's pouch but involves the submucosa of the rectum, in which it may spread widely. The infiltrated area is more or less fixed and is shelf-like or peg-like. The mucous membrane over it is not ulcerated. This absence of ulceration and the peculiar shape distinguish the rectal shelf from primary cancer of the rectum. Further, blood and pus are not passed. It is possible to mistake other conditions for the rectal shelf. The lower fold of Houston is sometimes thickened, but this should not cause confusion, as there is not the board-like feeling of the rectal shelf. In one case Dr. Blumer was deceived by a small subperitoneal myoma which projected into Douglas's pouch and impinged on the rectal wall. The clinical value of the rectal shelf varies. In some cases it merely confirms the diagnosis; in others it is of great diagnostic and prognostic value. It may point to a latent growth in the abdomen. In the great majority of cases the primary growth is in the stomach; in nearly all the cases the patients are males. In females cancer cells gaining access to the peritoneum tend to become implanted in the ovary, producing metastasis there. Dr. Blumer has found the rectal shelf in five out of nine cases of cancer of the stomach. It is of bad prognostic import, for glandular metastases are almost certainly present and radical operation is contra-indicated. When the primary growth is latent the metastasis has been taken for it and has even been excised as cancer of the rectum. Symptoms of rectal obstruction may be marked.

ENGLISH URBAN MORTALITY IN 1908.

THE death-rate in England and Wales during last year did not exceed 14·7 per 1000 of the estimated population; it was considerably lower than the rate recorded in previous years since the commencement of civil registration in 1837, and was 1·4 below the mean rate in the period 1899–1907, during which steady decline in the death-rate was almost constant. The recent issue of the Registrar-General's Annual Summary for 1908, a valuable contribution to vital statistics, contains much comparable information relating to the health conditions of our principal urban populations during last year. The population of the 76 English towns, which had at the date of the last Census upwards of 50,000 inhabitants, was estimated at sixteen and a quarter millions in the middle of last year, among which population the death-rate in 1908, after correction for its age and sex constitution, was equal to 15·8 per 1000, against 16·7, 16·9, and 16·3 in the three preceding years 1905–6–7. The corrected death-rate last year in the individual towns ranged from 9·5, 10·7, and 10·9 per 1000 in Hornsey, Leyton, and King's Norton, to 20·3 in Manchester and in Rochdale, 20·5 in Liverpool, 21·5 in Middlesbrough, and 22·3 in Oldham. In the county of London, with an estimated population little short of five millions, the corrected death-rate did not exceed 14·5 per 1000, the crude rate being only 13·8. It is worthy of note that, with the exception of Hastings, all the seven towns which had a corrected death-rate last year below 12 per 1000 were suburban town districts either of London or Birmingham; and further, that of the 15 towns in which the corrected death-rate exceeded 19 per 1000, eight are situated in Lancashire. The crude or uncorrected rate of mortality within the whole registration county of Lancashire is returned in the annual summary as 16·9 per 1000, against 14·7 in England and Wales, but this rate considerably understates the real excess of mortality within this county. The rate of infant mortality in Lancashire last year was equal to 144 per 1000 births, the mean proportion in England and Wales being only 121; the rate in Lancashire was indeed only exceeded in the counties of Durham and Glamorgan, in which it was equal to 148 and 151 per 1000. There are few surer tests of the relative sanitary condition of a population than the rate of infant mortality, which shows a marked excess in most of the larger Lancashire towns. The 76 large English towns having in 1901 a population exceeding 50,000 include 15 in Lancashire; in the aggregate of these 15 towns the rate of infant mortality last year averaged 148 per 1000, while the mean rate in the 61 other large English towns did not exceed 124, and in the County of London it was but 113 per 1000. The lowest rates of infant mortality among the 15 Lancashire towns were 111 in Barrow-in-Furness, 122 in St. Helens, and 129 in Bury, while in the 12 other towns the rates ranged upwards to 151 in Manchester, 152 in Salford, 153 in Preston, 156 in Wigan, 159 in Oldham, 168 in Rochdale, and 200 in Burnley. Among the towns situated in other parts of England and Wales the rate of infant mortality did not exceed 95 in Coventry, 96 in Northampton, and 99 in Portsmouth and in Reading; whereas it was equal to 166 in Hanley, 168 in Stockport, 178 in Merthyr Tydfil, and 184 in Rhondda. These wide variations in the rate of infant mortality in the large English towns, to which the Registrar-General's returns constantly draw attention, afford the strongest proof that infant mortality is within the control of sanitary administration, and the relatively high death-rates, especially among infants, prevailing in the Lancashire towns and in some other large urban districts undoubtedly reflect unfavourable sanitary conditions, which await increased efficiency in local health administration.

PERSISTENCE OF THE CRANIO-PHARYNGEAL CANAL IN ACROMEGALY.

THE cranio-pharyngeal canal, which passes down from the floor of the sella turcica through the basisphenoid into the nasal pharynx, normally becomes obliterated in the fœtus at the beginning of the third month. In 4829 skulls it was noted by Le Double to be persisting in only ten, about 0·2 per cent. Schlaginhaufen observed it, on the other hand, in 40 per cent. of apes' skulls examined. The interesting fact now comes to light that Dr. Ettore Levi of Florence has found it persisting in the skulls of two acromegalics which he has had the opportunity of observing, and he describes the condition in the *Revue Neurologique* for May 15th. In one, situated mesially and at the junction of the anterior and middle third of the floor of the sella turcica was a round depression 6 millimetres in diameter and 6½ millimetres deep; at the bottom of this was a small round opening which communicated by a canal 9 millimetres long through the basisphenoid with the nasal pharynx, entering the latter at a point 5 millimetres from the posterior margin of the left wing of the vomer, and allowing the passage of a seeker 1 millimetre in diameter. In the second case a canal in almost exactly the same site and with the same course was found. In this connexion it is instructive that in the skull of the Irish giant Magrath, described by Professor Cunningham, an elliptical perforation was noted in the floor of the sella turcica communicating directly with the nasal pharynx, the lower end of it being partly covered by the enlarged wing of the vomer. A re-examination of acromegalic crania in view of these facts is called for, as it is quite conceivable that an abnormality of this nature has escaped observation. The light which it may throw on the hypophyseal theory of acromegaly may be considerable. Recent researches have conclusively shown the existence of pituitary tissue in the vault of the nasal pharynx, deep in the soft tissues lining the vault, an accessory pharyngeal hypophysis identical in structure with the glandular part of the cranial hypophysis and of normal and constant occurrence. Its pathology is unknown, and what relation it may bear to those cases of acromegaly without obvious lesions of the pituitary gland, and those other cases of lesion of the pituitary without acromegalic symptoms, is equally unknown Data such as these suggest an interesting line of research for subsequent investigators

THE GOVERNMENTAL GRANTS FOR SCIENTIFIC RESEARCH

WE are informed that, in connexion with the annual grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease, Mr Burns, the President of the Local Government Board, has authorised the following special researches 1 A continuation of the investigation into protracted and recurrent infection in enteric fever, by Dr Theodore Thomson, medical inspector of the Board, in conjunction with Dr J C G Ledingham of the Lister Institute 2 A continuation of the investigation into protracted and recurrent infection in diphtheria, by Dr Theodore Thomson and Dr C J Thomas 3 A continuation of the investigation into flies as carriers of infection, by Dr S Monckton Copeman, medical inspector of the Board, and by Professor Nuttall of Cambridge 4 A continuation of Dr F W Andrewes's investigation on the presence of sewage bacteria in sewer air, with a view to ascertaining their number and the distance they can be carried by air currents, also a continuation of Dr Andrewes's investigation into the part played by changes in bone marrow in the defensive mechanism of the body against infection 5 A continuation of Dr W G Savage's investigations on the bacterial measurement of milk pollution and on the presence of the Gaertner group of bacilli in prepared meat and allied foods 6 An investigation into the chemical and physical changes undergone by milk as the result of infection by bacteria and into the relation of the pancreas to epidemic diarrhœa, by Dr H A Scholberg and Mr Wallis of University College, Cardiff 7 An investigation of the records of charitable lying in hospitals as to the nutrition of the mother and other factors influencing the vitality of infants and their progress in the first 14 days of life, by Mr G F Darwall Smith, physician to the British Lying in Hospital 8 An investigation into the occurrence and importance, in relation to treatment of mixed infections in pulmonary tuberculosis, by Dr A C Inman, pathologist to the Brompton Hospital for Consumption 9 An investigation on the relative importance of certain types of body cells in defence against the tubercle bacillus and the effect of tuberculin and other remedial agents on their activities, by Dr J Miller, pathologist to the General Hospital, Birmingham

FRACTURE OF THE SCAPHOID BONE

FRACTURE of the scaphoid bone of the wrist has received little or no attention in the text books and is regarded as extremely rare, but since the introduction of skiagraphy it is one of the injuries which have been revealed with unexpected frequency No doubt before the introduction of this means of diagnosis fracture of the scaphoid bone as well as many other lesions were covered by the diagnosis of "sprain of the wrist" Probably also this fracture has been mistaken for Colles's fracture or overlooked when that fracture was also present In the *Bulletin de la Société de l'Internat des Hôpitaux de Paris* for December, 1908, M Judet has reported the following case A youth, aged 20 years, was thrown violently from his bicycle against a wall The force of the injury was received on the palms of his hands, which he put out to save himself After the accident the lower part of the right radial region was swollen, and later the whole of the forearm A practitioner diagnosed fracture of the radius, which he treated by massage and progressive mobilisation Three months after the accident the patient came under the care of M Judet because of loss of use of the wrist and pains in the wrist All the movements of the wrist were painful and limited From time to time, especially at night, the patient felt neuralgic pains in the area of the median nerve The thenar and hypothenar eminences were slightly atrophied There was an enlargement of the wrist at its external part Palpation showed that this was due to bony enlargement which caused elevation of the region of "the anatomical snuff box" This sign enabled the diagnosis of fracture of the scaphoid bone to be made, which was confirmed by radiography The scaphoid was broken into two equal parts, of which the upper was displaced forwards and also had undergone a movement of rotation The semilunar bone had almost completely lost contact with the head of the os magnum In consequence of these changes a guarded prognosis was given The patient was told that he would have to remain under observation for a long time, and that if the stiffness of the wrist increased or if signs of compression of the median nerve appeared resection of the carpus might be necessary Massage, mobilisation, and baths were prescribed, and the treatment was energetically carried out After three months there was some improvement, but recovery was far from complete It would be of interest to record any parallel cases known to our readers

THE PHYSIOLOGICAL STANDARDISATION OF DIGITALIS

AN important contribution to our knowledge of the standardisation of preparations of digitalis has been made by Dr Charles W Edmunds and Dr Worth Hale[1] The introductory portion of the *Bulletin* contains a succinct account of the literature of the subject, from the chemical and pharmacological points of view, showing the variability of preparations of digitalis, and the impossibility of standardising them by a chemical assay of one or more of the active principles of the drug The literature relating to the various biological methods of standardisation occupies 16 pages and forms a most valuable summary of the subject It is shown that the various methods that have been employed fall into three primary groups, which may be classified as follows First a toxic method, in which frogs, guinea pigs, or some of the higher animals are used Secondly, a method based on the use of the frog's heart and the subsequent observation of the time that elapses before it stops in systole The third method aims at a comparison of physiological activity by means of the relative effects upon the blood pressure in some of the higher animals Dr Edmunds and Dr Hale examined a number of official and proprietary preparations of digitalis, in order partly to ascertain to what extent they varied in strength but more particularly to find if possible a method of standardisation which was capable of yielding uniform results and possessed advantages over other methods A superficial examination of the tables of results would seem merely to cast doubt on the value of the biological methods of assay now in vogue but a closer examination of the tables showed that the anomalies were exceptional the majority of the results being uniform It is pointed out that methods which employ as a standard the determination of the minimum lethal dose in the higher animals are not applicable to the physiological assay of preparations of digitalis because one solution might be very weak in its action upon the heart and yet contain decomposition products the typical action of which is upon the medulla. Preference is given for simple methods based upon the action of the drug upon the circulation rather than upon the nervous system, the two best being the "12 hour toxic method and the "one hour method," in both of which frogs are employed. Full details of these methods are given in the Bulletin, which will doubtless afford assistance to the compilers of the next British Pharmacopœia.

THE TUBERCULOSIS EXHIBITION: MR. JOHN BURNS ON "THE WHITE SCOURGE."

THE Tuberculosis Exhibition, already announced in our columns, was opened at the Art Gallery, Whitechapel, on Wednesday last, organised by the National Association for the Prevention of Consumption and Other Forms of Tuberculosis. The exhibition will remain open until June 19th, during which time lectures especially directed to arouse popular attention will be delivered by well-known authorities, while a conference will take place next week on the best methods for the prevention, early detection, and the subsequent treatment of consumption. The exhibition was opened by the President of the Local Government Board in a long and eloquent address in which he suggested that for the popular title of the "White Scourge," the far more poetical description, "Captain of the Men of Death" should be substituted, and truly the terrible figures quoted by Mr. Burns justify this use of Bunyan's phrase. But while these figures showed the drain on our national vitality caused by tuberculosis the future is one of great promise, as also appeared from Mr. Burns's statistics; for in less than 40 years the death-rate from phthisis has declined by more than one-half, while the better education of the people is leading them in every direction to live their lives and shape their domestic policy towards further improvement. In particular the public is now awake to the danger that lies in unwholesome milk, and here again Mr. Burns is to the fore by introducing a Milk Bill. The text of this measure, which we shall shortly publish in our columns, makes it probable, alas, that many of the clauses will be vigorously contested, but the debates, we may be certain, will take place over details and not over principles, for the country is now roused to the perils that lie in contamination of the staple food-supply of our young and our invalids. This wholesome feeling can only be advanced by such exhibitions as that which has just been opened at Whitechapel, and we are glad to learn from Mr. George Harwood, M.P., the chairman of the exhibition, that it is intended to send the exhibition to different parts of the metropolis and the country as a form of missionary enterprise. This proceeding has been attended in Ireland, as all our readers know, with highly satisfactory results.

THE TREATMENT OF CANCER BY FERMENTS.

DURING the last three or four years much work has been done in the treatment of inoperable malignant disease in man by means of the hypodermic injection of trypsin with and without amylopsin, but, though in a few cases some improvement appeared to follow, the ultimate result was unsatisfactory and the treatment has, we believe, been completely abandoned. Dr. J. A. Shaw-Mackenzie, who has worked on this subject, publishes in this number of THE LANCET a paper describing a series of experiments on the treatment of malignant disease in mice by means of hypodermic injections of extracts of the duodenal and intestinal mucosa, and of liver extract and also of mixed ferments. Control cases were kept. The result of the experiments has been that no definite beneficial action could be ascribed to any of the injections, though at one time it looked as if the injections had some influence. The failure of these attempts does not necessarily condemn all ferments in the treatment of malignant disease, but it inculcates the lesson that it is only by using a fair number of cases that we can arrive at a definite opinion; if only one or two cases be employed, an erroneous decision may easily be formed.

IT is intended to hold a short service on Friday, June 11th (Feast of St. Barnabas), at 1.15 P.M., at the Church of St. Magnus-the-Martyr, London Bridge, being the special effort of the united parishes of St. Magnus-the-Martyr, St. Margaret, New Fish-street, and St. Michael, Crooked-lane, E.C., on behalf of the hospitals. The preacher will be the Right Rev. the Lord Bishop of Rochester. The Right Hon. the Lord Mayor, accompanied by the Sheriffs of London, will attend in state. The collection will be for the Metropolitan Hospital Fund.

A SUPPLEMENT to the thirty-seventh annual report of the Local Government Board for 1907-08, containing the report of the medical officer for the same period, has just been issued.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L R.C.P. LOND.

Concerning the Budget.

AT present it seems unlikely that the rebate of half the duty on the quantity of petrol consumed in propulsion which is granted to commercial cars will be extended to automobiles used by medical men. It is, therefore, most essential to look that squarely in the face which the whole profession will regard as an unjust burden, and to take such means as we can to minimise the evil. Perhaps it may in an indirect way do us, or rather our motor cars, good. With automatic carburettors we may often be using more petrol than needful; this means too rich a mixture; a deposition of soot in the cylinders and piston-heads, with probably overheating, pre-ignition, and loss of power; all troubles that can only be treated by taking down the cylinders and curetting their insides. Now that petrol is 1*s*. 2*d*. the gallon we may perhaps be more careful, and although the pre-ignition knocks of our engine did not make us so, the Government's attack on our pockets may. If so, well, it is but another proof that "It is an ill wind turns none to good."

On top speed many engines run much better with an excess of air, and more air means less consumption of petrol and less liability to sooting. A simple way to bring about this condition is to cut two or three circular holes in the induction pipe as far away from the carburettor as possible, and, if practicable, equally distant from each inlet valve. Of course on some cars this latter cannot be done. The holes, about one-sixteenth to a quarter of an inch in diameter, should be guarded by fine gauze, and a sliding ring or sleeve should be fitted, so that on starting and on low speeds they can be closed. An ordinary tube slipped over the induction pipe and kept over the apertures by a spring answers admirably, and by means of a Bowden wire brought up to the dash-board, the tube, which should be just a close fit, can be drawn forward, and the extra air inlet so brought into use; on releasing the wire, the spring will pull the tube over the inlet and so close the openings.

We cannot produce petrol for ourselves, still, as I mentioned in THE LANCET of Jan. 9th, benzol is made in this country—in fact, in London, by the South Metropolitan Gas Company; and benzol with the carburettor air inlet widely open answers just as well as petrol. The one thing to remember when using benzol is to open the air inlet of the carburettor as much as possible and, what is even better, to make an extra one. If that is done there need be no fear of sooting and deposit in the cylinders.

A matter that will have to be settled is, Shall the tax be collected on the raw spirit as it arrives in this country or on the refined article as it is sent out in cans to the public? It looks rather as if the dealers expect to be charged on the raw material, for they have put the price up 4*d*., the extra penny being, I presume, for duty paid on spirit that is lost in distilling. As few medical men use cars of more than 16 h.-p. for the new tax, as pointed out in THE LANCET of May 8th, for annual motor-car licences, even allowing for the rebate, will not affect practitioners much, although those living in level towns and only using cars of 6 h.-p. will save a guinea a year by the alteration. It is to be presumed that the lower power [illegible] one on which [illegible] mula such as [illegible] will have to be adopted. Their method estimates the horse-power from the bore, irrespective of the stroke of the engine.

A Method to Keep Motor Vehicles Free from Dust.

A simple and effective device has lately been introduced by the Kennedy Motor Company, Limited, of Glasgow, which will certainly be a boon to those who drive in open cars. It consists of two fan-shaped spouts attached to the exhaust box of the engine, which so direct the exhaust gases that they meet the dust raised by the wheels and blow it away from the car and its occupants.

Removing Deposit from Cylinders.

[illegible] ders, [illegible] is to [illegible] the dome and the head of the piston. Prevention is better than cure, and provided that the mixture is not too rich, and the quality of lubricating oil used is good, and not excessive in quantity, this operation should not be needed more than once in every 18 months or two years. This scraping might not be then even needed if the combustion head or dome of the cylinder was machined perfectly smooth; in many cases these parts of the casting are left rather rough, and thus present a good surface on which deposit may settle. One of the features that calls for admiration in the sliding valve Daimler engine was the beautifully smooth inside of the head of these cylinders. But even with roughly cast insides care in the selection of the oil used will greatly assist in postponing the evil day when scraping will be necessary.

Choice of Lubricating Oils.

Because an oil is cheap it does not follow that it is not suitable; and the converse also holds true, even expensive oils are not always a success. Both hydrocarbon and compound oils have their advocates, but I believe the majority of experts recommend the latter class, believing that by their use decomposition and deposits of carbon are minimised. Anyway, oils with a flash-point not far below 500° F. are well suited, and a good test in addition to the flash is to put a little in a porcelain dish and weigh it, then place the dish with the lubricant in it in an ordinary kitchen oven for four hours and re-weigh; if the loss is under 2 per cent. and if the oil has become merely "tacky," that is, like treacle, it should do well for automobiles. Among many kinds that have a good name are the productions of Price's Patent Candle Company, Limited, Messrs. Butterworth of Liverpool, and the Anglo-American Oil Company.

THE SEVENTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

CONSIDERABLE activity has characterised the proceedings of the sections of this Congress after a brilliant opening ceremony which took place at the Albert Hall on May 27th.

The Prince of WALES, in declaring the Congress open, expressed his full appreciation of the important part which chemistry plays in almost every branch of modern industry and declared that experience has warned us that the rule-of-thumb is dead and the rule of science must take its place.

Sir HENRY ROSCOE, as Honorary President of the Congress, bid a hearty welcome on behalf of all British chemists to their *confrères* assembled from all parts of the world, a welcome which Sir WILLIAM RAMSAY cordially echoed in an address in which he briefly recounted the history of the Congress since its inception at Brussels in 1894. Dealing with the practical value of chemical science, Sir William Ramsay said that our continental fri[illegible] long seen and acted on the conviction that the prosperity of a country can best be advanced [illegible] friendship and constant association between the university and the factory, between pure and applied science. "Congresses like the present," he continued, "can teach us much and if we learn this lesson from them we shall have gained a valuable national asset."

Professor ARMAND GAUTIER followed with an expression of sympathy with the objects of the Congress on behalf of his colleagues in France. "The country," he said, "of the Lavoisiers, the Pasteurs, and the Berthelots was happy to come to offer a just tribute of homage to the country of the Cavendishs, the Davys, and the Faradays."

[illegible] Dr. HARVEY W. W[illegible] Dr. OTTO N. W[illegible] PATERNO, on behalf of Italy; and [illegible] the remaining countr[illegible] great importance to th[illegible]

As so often marks the organisation of international congresses, there proved to be a real plethora of papers and addresses, and many sections found it impossible to get through their programme i[illegible] impossible is it to give an [illegible] the various subjects disc[illegible] had important relations to medical science and administration. The question of food supply was, for example, discussed in many directions. Professor Bernthsen's remarkable summing up of the question of the world's supply of nitrogen attracted considerable attention. The production of nitric acid from the air on a tiny scale by Cavendish in 1781 had since received a mighty development, for at the present day hundreds of tons of nitrate available for the fertilisation of the soil were being manufactured with the agency of water and electric power, and it was probable that in a few years the annual output of air saltpetre would reach 100,000 tons. Such a consummation would appear to eliminate the view entirely that we are any longer at the mercy of natural processes for the production of fertilising materials.

Professor WITT of the famous Charlottenburg laboratories, in his able lecture on "Evolution in Applied Chemistry," referred to the same subject and instanced the case of *Norway, which had begun to develop a chemical industry of* vast dimensions. Its factories would have no chimneys and no fires. They would be actuated by the white coal, the force of roaring torrents. If we considered how our present chemical industries had been evolved from empirical processes such as our ancestors practised and as they still exist in the countries of the East, we could easily observe a gradual transformation similar in respect to the one that living nature [illegible] the present types of plant and [illegible] important duty to watch ov[illegible] the past and to collect it before it disappeared for ever.

In the bromatology section many interesting papers on food questions were discussed, and amongst them references were made to the vexed question of standards. Mr. F. W. BECK, who has given considerable attention to the legal aspect of the matter, thought that a general fixing of standards for natural products or articles of simple manufacture was of very doubtful utility, and that a standard was futile in the case of mixtures such as coffee and chicory and prepared cocoa. He expressed the opinion, however, that some better legislative control was needed in regard to the use of colouring matters and preservatives.

The position of English legislation and administration in regard to food was admirably summed up by Dr. G. S. BUCHANAN of the Local Government Board.

Mr. E. RUSSELL and Mr. F. W. F. ARNAUD suggested new standards for fat in milk based on the average monthly percentages obtained in the case of two large towns submitting more than 500 samples of milk for analysis annually. The authors suggest seasonal standards, as, for example, a 3 per cent. standard for four minimal months, raising this to 3·3 per cent. for other periods of the year. On a low figure for fat, such as 2 85 per cent., for the minimal period, this would be raised to 3·5 per cent. during the maximal period, the standard being 3·3 per cent. for the intermediate months. It is contended that these standards would at least render the task of the skilled adulterator more difficult in preparing "legal" from pure [illegible] the requisite quantity of separated [illegible] the same section it was agreed to [illegible] uct of distillation of the fermented juice of the grape" without regard to the kind of still in which it was obtained. Other articles of food were also considered and standards suggested. The consensus of opinion was in favour of the formation of a board of reference to deal with these questions.

Dr. W. H. WILEY in his paper on Food Control in the

United States pointed out that the Food and Drugs Act in that country was administered by the Secretary of Agriculture who, under the authority of Congress, established standards of purity. He said that the system worked well, the consumer being protected and the supplier unhampered.

There were several interesting topics discussed in the hygiene section, Sir JAMES CRICHTON-BROWNE taking Sewage Disposal and Disinfection as the theme of his presidential address. He pointed out that nature was constantly engaged in disinfecting the globe; the ocean was a pickle-tub, the air an indefatigable fumigator, and the sun a revolving incinerator. He pointed out also the importance of placing the supply of disinfectants under control in order to secure the sale of disinfectants of guaranteed germicidal efficiency.

Mr. A. WYNTER BLYTH, in a paper on the subject of Disinfectants, argued that the bacteriological test for disinfectants cannot be used alone for standardisation purposes owing to the want of agreement in the results obtained by different bacteriologists using the same standard method. He contended that chemical analysis should be combined with bacteriological tests.

In the same section there were some interesting papers, which we hope to refer to in a future issue, on such questions as the pollution of sea water by sewage, the better utilisation of sewage sludge, and the purification of streams. Space also for the present precludes us dealing with the many excellent papers on pharmacological subjects discussed in the pharmaceutical chemistry section. There were also a number of papers read on synthesis, analysis, helium, smoke, dust, and so forth, a further reference to some of which we hope to have the opportunity of making in the future. We agree with the *Times* that if congresses had as much respect for time as newspapers are compelled to have for space they would reform their programmes in the direction of brevity.

The proceedings were formally closed on Wednesday, when it was announced that a direct invitation had been received from the United States Government to hold the next meeting, which will be in 1912, in that country. The invitation was cordially accepted.

THE SECOND INTERNATIONAL CONGRESS ON THE CASUALTIES INCIDENT TO LABOUR AND INDUSTRY.

AFTER a brilliant inauguration on Monday, May 24th, in the Hall of the Horatii and Curiatii in the Roman Capitol, at which the spokesmen were the Syndic, Signor Nathan, the Minister of Public Instruction, Signor Rava, Dr. Guido Baccelli, and the President of the Organising Committee, Professor Salvatore Ottolenghi, the Congress, to the number of nearly 500 delegates, Italian and foreign, proceeded to the Policlinico, the great hospital outside the Porta Pia, and occupied the afternoon sitting with special business. The first paper was that of Signor P. Colajanni—an elaborate report on the "Organisation of the Medico-Chirurgical Service for the Cure and Surveillance of the Lesions incurred by the Labourer and the Artisan," in the course of which he dealt with the casualties incident to those employed in the Sicilian sulphur mines and gave a luminous account of the services, medical and surgical, organised in behalf of the sufferers, dwelling particularly on the working of the "Obligatory Syndicate of Mutual Assurance." Signor Colajanni's positions were well maintained in the ensuing discussion, which was followed by papers from German, Dutch, and French delegates, all contributing illustrations and suggestions gathered from special experience in cognate fields.

On the morning of Tuesday (May 25th) the Congress resumed business under the presidency of Dr. Thiem, representing Germany; Dr. Poëls, representing Belgium; and Professor Ottolenghi, Professor Tamburini, and the Commendatore Magaldi representing Italy. The main topic of discussion was the report on the "Organisation of the Medico-Legal Service in cases of Casualty and on the Guiding Principles to be followed by the Expert in Diagnosis." Dr. Becker, speaking from German experience, discussed the features of "simulation" in the casualties incident to labour and industry—"simulation" not the result of attempted malfeasance or deception. Dr. Miller (the reporter) contended that the rules laid down for expert guidance in the law of June 30th, 1900, were only sufficient for the more necessary requirements in protecting the "diritto d'assicurazione" (right of insurance companies), and did not suffice for "questioni giudiziarie" (questions before the law courts). Descending to points of detail, the Congress heard with interest the remarks of Dr. Giuseppe Gradenigo, professor of oto-rhino-laryngology in the University of Turin, who deplored the incompetence of non-expert dealings with injuries of the throat, ear, and nose, illustrating his position with concrete examples, a position reinforced by Dr. Poëls, who also maintained the necessity for more specialised knowledge and experience on the part of practitioners called in on occasion of indemnity for lesions incurred in the industries. Third in order on the agenda paper came the topic headed "Ascertainment and Prognosis of Neuroses in Casualties Incident to the Labourer and the Artisan." On this the chief spokesman was Dr. Cesare Biondi, professor of legal medicine in the University of Cagliari (Sardinia), who dwelt on the early or precocious symptoms of the neuroses in question, and was followed by Dr. Poëls and Dr. Tamburini, professor of psychiatry, theoretical and clinical, in the University of Rome, the latter of whom contributed much interesting illustration of the "traumatic neuroses." Dr. Biondi, after a rather searching crossfire of questions from other delegates, French, German, but mostly Italian, maintained his positions in a highly effective speech, and sat down amid applause.

The business of Wednesday, May 26th, turned primarily on the "Estimate of the Capacity for Work before and after Lesion," the first delegate to intervene in the discussion being Professor Carrara of Turin, who contended that in many ailments attributed to casualties in the factory or the field it was impossible to diagnose, in a manner medically sound, the nature and extent of the particular lesion. Professor Imbert of the University of Montpellier spoke on the legal difficulties in assigning compensation for injury, and was followed by Dr. Poëls, who animadverted on the want of method and system inherent in existing legislation for making the "estimate" in question. Dr. Treves of Milan added other considerations in a cognate sense, and pointed out that in estimating the victim's capacity for work before or after injury the expert should take into account the "ambiente" (surroundings, material and moral) of the industry or labour in which the said victim was engaged. At this point Dr. Mennella (medical major in the army) gave instances of how the lesion, when traumatic, perverts the functions of the nervous system and affects, pathologically, those of the viscera by vaso-motor disturbance—the digestive and genito-urinary apparatus being so involved as to cause "auto-intoxications" which aggravate and prolong the post-traumatic effects and give rise to many symptoms, neurotic and psychical. Dr. Liniger, who holds the chair of Social Medicine at Düsseldorf, urged the necessity, in estimating capacity for work after injury, of supplementing the examination of the practitioner called in by that of another with a view to "check," so as to arrive at a less disputable judgment, and, following up his contention, he drew a strong distinction between the direct and the indirect consequences of injuries sustained. From this stage the discussion expanded over a wide area, Dr. Le Noir of Paris incurring the adverse criticism of Dr. Reclus, who argued that the injured operative should be indemnified in proportion to impaired capacity for work without consideration of the possible effects of pre-existing ailments in modifying the nature and consequences of his injury.

After many opinions, *pro et contra*, had been heard, the Congress left the subject unsettled and passed to the next topic dealing with the "Influence of the Forms of Indemnification on the Estimate of Post-traumatic Nervous Disorders," which again proved fertile in controversy. Dr. Oettinger said that "the nervous phenomena observed after traumatic lesion have become even more frequent since the passing of new laws on the casualties in field and factory"—in abatement of which fact he recommended that the "juridical position" of the injured operative should be fixed with least possible delay and that a "small fund of indemnity" should be instituted *ad hoc*. Dr. Lombroso of Florence urged the importance of losing no time in paying the indemnity as soon as the "malattia nervosa post-traumatica" had been ascertained. Again the discussion diverged into subtleties more [illegible] not without a sense [illegible] Adaptation of [illegible] tizzati). This proved a most interesting theme, in the discussion of which the successes of the mechanician working in concert with the surgeon were conspicuously in evidence. Finally, at its closing sitting, on May 27th, the Congress [illegible] views which this theme evoked reference must be made to the official "Resoconto" shortly to be published, as well as for the subsidiary communications submitted in supplement to *the seven main topics dealt with on the agenda paper.*

Thus closed a highly successful Congress on one of the most important subjects of the day, involving issues of the deepest interest to Labour, Industry, Capital, and Science, whether social, medical, or surgical. An eloquent valedicdictory discourse from [illegible] by a motion on the part of Dr. [illegible] as the seat of the next Congress. [illegible] mation and the delegates thereafter proceeded "from labour to refreshment" in the form of a sumptuous banquet in the Hôtel Excelsior.

HEALTH OF THE CITY OF LONDON.

WE are indebted to Dr. William Collingridge for a copy of his recently published report as medical officer of health of the City of London. In this report, which is the ninth by the present writer, the sanitary condition of the City in recent years is compared with that obtaining in the middle of last century—very much, we doubt not, to the gratification of the City Corporation. In connexion with the vital statistics of the City, the first matter to claim attention is the unique character of its population. Dr. Collingridge reports that some persons who desire to belittle the importance of the City frequently allude to it as of only one square mile in area, with a decreasing and insignificant population. To this calumny the report supplies the sufficient refutation that whilst the number of persons passing the night within the City is probably less than 20,000, the number congregated on that area during the daytime is estimated to exceed 385,000. Of the magnitude of the assemblage of human beings that daily takes place in the City some idea may be gathered from a further statement in the report that the number of persons known to have entered and left the City on one day alone in May, 1891, was not less than [illegible] to the foregoing facts, and especially [illegible] properly urges upon his sanitary authority the necessity of ascertaining, by actual enumeration, the number of persons resident in the City during the working hours of the day. Dr. Collingridge tells us that the taking of the first day census of London was decided upon by the City Corporation in the year 1866, a special committee of which reported, at the time, as follows:—

> The Imperial Census taken decennially under the authority of Parliament affords no indication whatever of the actual population of the City, and every recurring census only leads further astray in this [illegible] wealthiest commercial emporium to be found in the world.

In view of the near approach of the next Imperial Census year, and having regard to the desirability that no time should be lost in making the necessary preliminary arrangements, the medical officer of health recommends that provision should be made for the day enumeration above referred to at or near the date of the next Imperial Census taking—i.e., in 1911.

Very remarkable is the improvement that has taken place *in the health and sanitary environment of the citizens of* London within the last 60 years. In order to appreciate the growth of reform it will suffice to compare with the state of things now happily existing the deplorable conditions of life in the metropolis in the days of Sir John Simon, the first medical officer of health. Reporting in 1849, Sir John Simon stated that "as far as could be ascertained there were within the City some thousands of houses with cesspools attached to them, and that the supply of drinking water was only a fraction of what it should be. Thousands of the people had no supply of water to the houses in which they dwelt. For possession of the first necessity of social life such persons wholly depended on their power of attending, pail in hand, beside the nearest stand-cock, where, with their neighbours, they waited their turn during the tedious dribbling of a single small pipe." Again, in referring to the conditions then prevailing in tenement houses he wrote: "It is no uncommon thing, in a room 12 feet square or less, to find *three or four* families *styed* together (perhaps with infectious disease among them) filling the same place day and night—men, women, and children in the promiscuous intimacy of cattle. Of these inmates it is nearly superfluous to observe that in all offices of nature they are *gregarious and public*; that every instinct of personal or sexual decency is stifled; that every nakedness of life is uncovered there. Who can wonder at what becomes, physically or morally, of infants begotten and born in these bestial crowds!" A cursory perusal of the present report will suffice to show how vast is the improvement that has been effected in all that concerns [illegible] citizens of London [illegible] mation of new [illegible] the demolition [illegible] llings for the working classes has been willingly met by the ratepayers. In no other town at the present day is the work of public cleansing more thoroughly attended to, and nowhere is sanitary accommodation for visitors better provided for. Without a pure and plentiful water-supply no community can be held to be living under satisfactory conditions of health or even of cleanliness. Dr. Collingridge reports that the citizens have no reason to complain of the quality of the water supplied to the metropolis, but that they do complain bitterly of its cost. In consequence of what is considered unfair taxation in this regard, a considerable number of artesian wells have been already sunk in the City, and many more are now in process of construction. In every instance in which the water from these wells has been examined the public analyst has testified to its excellent quality.

The character of the food-supplies of the City received special attention during the year under report. We are not surprised to hear that the due supervision of the quality of the meat and other food which in enormous quantity passes through the City markets entails heavy responsibility on the sanitary staff, and this responsibility has been further augmented by the issue of new regulations by the Local *Government Board.*

The milk-supply of the City has been kept under constant supervision, and the milk arriving in London for delivery to dealers in the City has been subjected to bacteriological and chemical investigation by the officers of the health department. Very full, if *somewhat startling*, particulars are given in the report concerning the analysis of milk samples in each of the last four years, the results of examination being tabulated under the following heads: (1) fairly clean and pure; (2) unclean; and (3) tuberculous. Notwithstanding the publicity given in recent years to the details of analysis of milk by the public analyst, the present report shows that even in the year 1907 not less than 37 per cent. of the *samples analysed* were returned as "unclean," whilst 8·3 per cent. were returned as "tuberculous." The proportion *of tubercle-contaminated milk in the City supply* appears to have been practically constant in recent years, and it is important to note that in every case in which milk has been condemned as tuberculous the bacteriological result has been confirmed on examination of the herd of cows producing it. There is little reason to look further afield for the causes of human tuberculosis, unless the degree of contamination in the milk-supply of London is enormously greater than that of the country generally. The value of bacteriology as a means for determining the presence or absence of disease in *milk is abundantly shown in the present report*, and it is not a little surprising to learn that practically no precautions are even yet taken by either farmers or wholesale dealers to ensure that the milk shall not be a vehicle for the conveyance of tuberculosis.

Dr. Collingridge is clearly of opinion that the control of milk-supplies is a matter for the supreme authority of the Board of Agriculture and Fisheries, whose business it should be to see that the Dairies, Cowsheds, and Milk-shops Orders are effectively carried out by those responsible for their administration. While the best method of controlling the milk-supply is undoubtedly at its source—viz., the farm, there is no real difficulty in effecting this on the spot by the local authority, for upon bringing the facts to the notice of the local medical officers of health steps have promptly been taken in every case to improve the local sanitary conditions of the farm concerned. This indicates that there is no necessity for a central authority to waste time and money in inspecting country farms where their intrusion would be resented, all that is necessary being for each urban authority to maintain strict supervision over the purity of the milk supplied to the district, and where this is unsatisfactory to communicate at once with the local authority and also with the Board of Agriculture and Fisheries. Dr. Collingridge questions the wisdom of the London County Council in its present attempt to acquire powers for examining milk at the metropolitan railway stations with a view of preventing the distribution of dirty milk. Obviously it would be better to eliminate the risk of danger at the farm than to seek to control it after delivery in London. He expresses his conviction that piecemeal legislation of this kind can never be effective, and that the only satisfactory way of dealing with this question is for the Government to proceed at once with the long-promised general measure dealing comprehensively with the subject. In this connexion it is satisfactory to note that last week Mr. John Burns introduced into the House of Commons his promised measure entitled "The Milk and Dairies Bill," which seems likely to be effective provided that it eventually obtains a place in the Statute Book; some of the provisions, however, will provoke opposition. And however thorough may be the supervision of the milk farm, there are other factors prejudicially affecting the wholesomeness of the milk during its transit to London. For example, the churn in common use is sadly ill adapted for its purpose, as it affords a resting-place for filth which readily obtains access to the milk through the ventilating apertures in the lids. Moreover, the churns are often returned to the farmers unscalded and even unlocked, so that there is no guarantee that even ordinary cleanliness has been observed. Again, the practically universal system of mixing at the metropolitan railway stations necessarily leads to exposure of the milk to contamination by the dust constantly present in the atmosphere of a great city. At the stations the milk is treated with a "rouser," which has often been allowed to stand on the dirty platforms; and the mixing is conducted by the operator, who plunges his naked arm into the churn, transferring some of the milk to another vessel. In these several ways the milk runs the risk of serious pollution before delivery to the consumer, who, seldom adopts the precaution of boiling it before use as food.

Of the investigations undertaken during the year for the detection of obscure disease, and of the administrative measures adopted for the protection of the public health, the report contains full and very instructive particulars. Among these the most far-reaching and important is the investigation which was undertaken with the aid of Dr. Klein, and which establishes the value of bacteriology as a means of elucidating difficult sanitary problems. Dr. Collingridge gives account of an outbreak of illness occurring in a large business establishment in the City in which a large number of persons became seriously ill, apparently as a result of ingesting a quantity of "vermin destroyer" which had in some way got mixed with their food. In every case the illness is described as having been very severe, although happily not fatal, the patients having recovered by the end of a week from attack. What is particularly important from a public health point of view is the fact that examination of the excreta of the patients showed the presence of the same bacterium which is contained in the vermin destroyer and which is stated to be fatal to rats, mice, and other rodents, but to be harmless to domestic animals and to human beings! In view of this investigation the truth of the latter clause of the statement would appear to be more than doubtful. Indeed, a representation has already been made to the Government, as a result of which it is hoped that some restriction will be placed on the indiscriminate sale of vermin poisons of this nature.

The usual tables of vital statistics are included in this report, and Dr. Collingridge is able to report a death-rate for 1908 of only 12·6 per 1000 of the population; this rate is almost identical with the rate of the preceding year, whilst that of the entire County of London was 13·8.

The useful standard tables issued by the Local Government Board are appended, and especial prominence is given to the infantile mortality table, which shows the loss of life from the principal causes at the several stages of the first year of age. Measured in terms of total births the deaths of infants under the age of one year were only 65 per 1000, as against 113 per 1000 for the whole of London.

SANITATION IN INDIA.

VI.[1]—JAILS (*continued*).

Burma.

THE report for the year 1907 on the Prison Administration of Burma is furnished by Lieutenant-Colonel G. J. H. Bell, I.M.S. The number of jails in this province are six central and 24 district jails. At the beginning of the year the total number of prisoners of all classes in confinement was 14,129, an increase of 901 over the corresponding numbers for 1906. During the year, however, there was an actual decrease of 1201 in the number of prisoners admitted, the numbers being respectively (for 1906 and 1907) 35,674 and 34,473.

We are glad to note that a wise reform in the jail administration has now been perfected—namely, the segregation of juvenile criminals from the rest of the jail population, whilst arrangements are also being made to provide separate accommodation for juvenile first offenders and juvenile habituals. The jail at Meiktila has been set apart for this purpose. Certain structural alterations require to be made in this jail, the details of which are being worked out by the Public Works Department; the jail when altered will provide separate accommodation for 100 juvenile first offenders and 50 juvenile habituals, thus supplying a long-felt want; for these new arrangements should add very largely to the reformatory and educational character of sentences of imprisonment passed on juvenile offenders. With regard to the number of these prisoners in the year under review they fell from 171 in 1906 to 89 in 1907. Another fact that should be noted is the general decrease of 54 in the number of offences of assaults and mutiny. This, though not so large as in the preceding year, is still very satisfactory. Rangoon, however, showed a very marked increase in this class of offence—viz., from 50 in 1906 to 178 in 1907. The superintendent of the jails reports that the assaults were not due to any combination amongst the prisoners, but that each case was an attempt apparently to take revenge for a private grudge or was due to sudden outbreaks of temper.

Coming now to the vital facts relative to the jails in Burma it is evident that wise forethought has been exercised in this direction. With regard to the water-supply samples were sent to the chemical examiner for analysis, and when the report thereon was unfavourable steps were taken to remedy the defects. In several jails the drinking water is boiled. Water drums fitted with taps and locks are being supplied, only two jails remaining without them. Other means of ensuring a good water-supply were the improvement of existing filtering arrangements. Thus at Thayetmyo a masonry cistern for cooling the filtered and boiled water was provided and brought into use in August, and as one cistern was found to be inadequate the provision of another was approved of. At Myingyan the excessive amount of total solids in the drinking water has been suspected of being the cause of cases of muco-colitis. Over-concentration by prolonged boiling probably had the result of increasing this defect, and care is now taken that the water is boiled only for 10 minutes. At the Rangoon jails the chief source of the water-supply therein was pronounced by the chemical examiner to be unfit for drinking purposes owing to the presence of organisms of the coli group and its use was discontinued for the greater part of the year The water has, however, been now declared to be fit for drinking It may be mentioned also that the Inspector General acknowledges a plan furnished to him by Colonel King I M S , the Sanitary Commissioner, for an overhead shower-bath for use in jails Lieutenant Colonel Bell has introduced this system for trial into one of the sections of the new jail at Moulmein, and should it be found satisfactory and not too expensive its use should be extended to the other jails Regarding the employment of the prisoners, some difficulty in obtaining a sufficient amount of hard labour was experienced in certain of the jails Wheat grinding provides a most suitable form of labour for a large number of prisoners Stone breaking in the Rangoon jail has had to be discontinued on account of the removal of the municipal stone depôt to a site to which the prisoners could not be sent the expense involved in carting the stone to and from the jail being too prohibitive Lieutenant Colonel Bell regrets that this excellent and remunerative form of hard labour, which had for many years employed a large number of prisoners, has been unavoidably lost to the jail department

---

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of April 10th (p. 1067) and 24th (p. 1199), and May 1st (p. 1269), 15th (p. 1412), and 22nd (p. 1480), respectively.

With respect to the lines on which the conservancy arrangements are being carried out, the Inspector General finds that the latter are efficiently performed He also has wisely, we think, not discontinued the system of mounding excreta previous to their use as manure in certain of the jail gardens This system has had the approval of his predecessors in office for many years, and with proper precautions has always been found successful

Coming now to the sickness and mortality experienced in 1907 in the jails of Burma, we find that though the daily average number of prisoners in confinement rose from 13 370 to 13 721, the number admitted to hospital decreased from 3736 to 3506, the daily average sick from 211 to 190, and the deaths from 198 to 163 The ratio per 1000 of average strength as regards admissions to hospital fell from 297 43 to 255 52, of daily average sick from 15 78 to 13 85 and of deaths from all causes from 14 81 to 11 88 as compared with 1906, showing that the standard of health in 1906 has been more than maintained during the year under review, the ratios of admission, daily sick, and deaths to daily population during 1907 being the lowest recorded since 1892 There has been a remarkable change for the better in the case of some of the jails Thus Thayetmyo, which for two years showed the highest death rate in the year under review occupies the lowest place, the ratio being now 3 65, as compared with 28 99 in 1906, although the daily average population increased from 759 to 821 Moreover, in none of the causes of death reported could any influence of jail life have been the cause, the causes being leprosy, volvulus, and erysipelas The superintendent of the jail, Major E A L Hammond, I M S
improvement to
year of his hospi
Bell, we are glad to note, strikes the right nail on the head when he states that the careful management of the sanitary and medical work of the jail by Major Hammond must have largely contributed to the satisfactory result that has been gained In another of the jails—viz , Myingyan—showing these excellent medical results the superintendent does not take any credit to himself , but it is evident that such good results could not have been obtained without great care and attention both by the superintendent, Lieutenant Colonel Stewart, and his hospital assistant Lieutenant Colonel Bell likewise praises Dr Hollingsworth the superintendent of the jail at Myaungmya, for his creditable management of the jail

As regards the chief causes of sickness and mortality in 1907, there were four cases of cholera, three proving fatal All were imported cases and one in particular showed the value of the segregation of new admissions The prisoner in question was received on transfer from another jail, placed on arrival in the segregation shed outside the jail and whilst there developed symptoms of cholera and died within 24 hours He was stated to have received some food from a hawker at the Pegu railway station cholera being then prevalent at that station Dysentery gave a slight increase in the number of admissions—viz , from 223 to 256—but the number of deaths was only seven as compared with 18 in 1906 With regard to the causes of the disease in one jail, as before remarked, the cases were most likely not dysentery, but muco colitis, possibly due to the already large proportion of solids in the drinking water having been increased by concentration through over boiling , although the Inspector General thinks it probable that some cause other than the quality of the drinking water may be found for the occurrence of these cases In those jails where there has been a reduction in the number of cases this has evidently been due to the superintendents being fully alive to the necessity for strict precautions being followed with regard to segregation of dysentery patients, the protection of drinking water from contamination, the use of separate clothing, beddings, and utensils, and the disinfection and destruction of all excreta and refuse food Malaria showed a noteworthy reduction in the number of cases , thus in 1905 there were 632 admissions , in 1906 635 admissions , but in 1907 only 489, or a ratio of admissions per 1000 of average strength of 52 88 50 37, and 37 59, and of deaths of 0 59, 0 48, and 0 23 With reference to this striking decrease it is to be noted that there were no extraordinary meteorological phenomena in 1907, the rainfall was fairly well distributed and of a good quantity In 1906 the rains had been light, and the superintendent of one jail, Akyab, held that this had had something to do with the increase The prophylactic use of quinine certainly was of value in reducing the number of cases, and is fully recognised The method in use is that every prisoner who is believed to have suffered from malaria is given 10 grains of quinine twice weekly, and the treatment is continued until it appears that the prisoner is free from malaria A register of the cases is carefully kept As regards the diagnosis of the cases returned as malaria, blood examinations were systematically made in all cases of fever, and in by far the large majority of cases returned as ague the presence of the malarial parasite was demonstrated, whilst in the few cases in which it was not the symptoms were so typical as to leave no doubt of the disease Captain H H G Knapp I M S , the jail superintendent, Rangoon, has evidently followed the example of Colonel W J Buchanan, I M S , who some years ago trained certain of the convicts to diagnose the organism microscopically The increase of the number of cases in this jail, where malaria is only returned as such when the organism has been found is evidently partly due to the greater degree of skill possessed by the convict who conducts the microscopical examination Tuberculous diseases showed a fall in the number of admissions and deaths being 68 and 43 respectively, as compared with 114 and 54 in the previous year Great attention is paid to prophylaxis in these cases, and in this respect the Inspector General draws attention to the necessity of seeing that each patient's blanket is kept exclusively for his own use, and also for the careful washing and disinfection of all blankets when in use and when received back into store The work of disinfection is rendered easy by the use of Thresh's disinfectors one of which has been supplied to each jail Proposals for the construction of a separate jail or ward as an annexe to one of the existing jails in the dry zone, for the accommodation of 50 prisoners suffering from tuberculosis but to be made capable of further extension, have been submitted to Government but are still under consideration It is much to be desired that the necessary sanction be granted With respect to the cases returned as "simple continued fever," the Inspector General states his opinion that not a few of these are due to tuberculosis There can be little doubt we think, but that he is right In many parts of India cases occur in which for some days, or even weeks no thoracic signs are found and which suddenly light up into acute tuberculous affections of the lungs This has been especially noted to occur in the case of Goorkhas Plague, notwithstanding its prevalence in many districts, gave only two cases in the Burma jails during the year , one of these (a bubonic case) was at once recognised on his arrival at the jail gate by the hospital assistant During the year steps were taken to render the grain godowns in or attached to jails rat proof and at the close of the year the work in 19 jails had been completed and estimates had either been sanctioned or were in preparation for the remaining jails The Inspector General tenders well deserved praise to the superintendent subordinate medical staff and jailers for the success attained in keeping the jails free from the disease during the year The report concludes with the usual appendices

EGYPT IN 1908.

Sir Eldon Gorst's second annual report on the progress made in the various departments of the Egyptian Government is, like its precursor, drawn up for the year 1908 in accordance with the model established by Lord Cromer, and, unlike most official documents, is consequently as easy to read as it is full of information; but although the sum total of the latter is, generally speaking, satisfactory, it is disappointing to learn that the working of the existing institutions by which the people are already associated with the functions of government is by no means all that could be desired, and that the Legislative Council and General Assembly are losing ground, the part played by these bodies in the administrative system of the country being less efficiently performed than heretofore. The first subject dealt with by Sir Eldon Gorst with which we are more particularly concerned is the census of 1907. The number of persons enumerated in the ordinary way was 11,189,978, including 147,334 foreigners. The Bedouins, who live scattered over vast and more or less desert tracts, and are not collected in any considerable number at definite points, were not enumerated, but estimates of their strength, amounting in the aggregate to 97,381, were furnished by their Omdehs, or head men, the total population of the country being thus brought up to 11,287,359 individuals divided into 5,667,074 males and 5,620,285 females. In 1897, when the previous census was taken, the number of inhabitants, according to a corrected statement, was 9,717,228 persons of both sexes (including eunuchs); the increment during the ten years was consequently upwards of a million and a half, which gives an annual augmentation of 1·6 per cent.[1] The inhabited areas of Egypt being equal to about 12,000 square miles the density of the population, omitting the sparsely peopled desert regions, was 939 per square mile. This largely out-distances all the European countries, the nearest approach to it being the 588·7 per square mile of Belgium, and, as Sir Eldon Gorst observes, "It seems probable that nowhere outside Bengal will an area of like size be found carrying so dense a population of a similar non-industrial character." Egyptians are essentially a gregarious people, isolated dwellings being very rarely met with. The vast majority of the population is spread over two cities, 43 towns, and 3581 villages. The number of inhabitants per 100 houses is returned in this census as 581 for the country as a whole, the range extending between 319 and 947. The total number of inhabited houses is 1,927,352 as compared with 1,418,891 in 1897. The house was the smallest structural unit dealt with except in Cairo, Alexandria, and Port Said, where an attempt was made to ascertain the number of living rooms per house. The data obtained, Sir Eldon Gorst fears, are not very trustworthy, but so far as they go are interesting. "If they are to be believed," he continues, "overcrowding is present in three out of the 13 divisions of Cairo. The English standard of overcrowding is a house containing more than two persons per room, and in six divisions is this proportion exceeded. …… Turning to Alexandria we find that three out of the seven divisions are overcrowded. …… The density of Port Said is 198 persons per 100 rooms, just below the overcrowding limit."

Public Health.—In 1908 there were in Egypt 21 general hospitals open to the public and containing 2153 beds. The number of in-patients treated during the year was 33,241. In 1888 there were 20 hospitals open, but the number of patients treated in them was only 11,834. The number of out-patients seeking relief in 1908 was 181,580, but in 1888 this service was non-existent except at Kasr-el-Aini, where an out-patient department had been inaugurated a year or two previously. Sir Eldon Gorst adds that, "in addition to the provision of hospitals, efforts are being made to bring simple medical aid within the reach of the people in the more remote villages, and with this object the Sanitary Department is instituting gradually in every district fully equipped dispensaries and first-aid establishments, under the direction of the local medical officer. There are at present 48 of these dispensaries, and the total number of applications for assistance was 38,000, as against 24,500 in 1907." Dispensaries on the lines indicated were first started in 1887, when seven establishments were opened in suitable localities. The following year three more were opened, and in 1889 there were altogether 13 in active operation. The travelling ophthalmic hospitals instituted by Sir Ernest Cassel have now become a branch of the Public Health Department, and according to Sir Eldon Gorst "it may be hoped that in time permanent eye hospitals will be established in all the larger towns, combined with travelling hospitals for the country districts. During 1908 7764 patients were treated, and the number of cases refused on account of lack of accommodation was 10,445." The permanent eye hospital at Tantah built by the Government was completed and opened to the public in November. At Assiout, where the inhabitants have subscribed £E5000 for the purpose, it is hoped that a new ophthalmic hospital will be opened shortly; and at Mansourah, where a local notable has contributed a similar sum, there is every prospect that a permanent institution for eye affections will soon be completed. In this connexion it may be mentioned that the Egyptian Government has recently decided to support the annual cost of maintaining all such hospitals as may be constructed by private enterprise. In a note submitted by the Financial Adviser and quoted by Sir Eldon Gorst we find it stated that an additional sum of £E17,340 has been allocated between the Government hospitals and prisons in the Budget for 1909; and also that £E33,000 have been provided for the construction of the new lunatic asylum at Khanka and for increasing the accommodation at the Abbassieh Asylum.

For the long-delayed Cairo drainage scheme a grant of £E70,000 has been authorised; and as the consent of all the Powers to an augmentation in the house tax of the city from 8 to 10 per cent. has now been received there is at least a good prospect that this most necessary work will soon be commenced. The important subject of a good water-supply for the capital of Egypt is still under discussion, but it is hoped that within a reasonable time a definite conclusion may be reached.[2] Means have been found to secure the removal of iron and manganese, but the water still remains too hard and has not as yet attained to a standard "approximating in character to that of the Nile." In the second city, Alexandria, the great question of drainage is still in abeyance. Sir Eldon Gorst says that an approved scheme has now been completed, but until some way of raising funds for its execution can be found this essential work cannot be proceeded with.

(To be concluded.)

Public Health.

ANNUAL REPORTS OF SCHOOL MEDICAL OFFICERS.

The City of Exeter.—The inspection of the school children in this district is carried out by Mr. P. H. Stirk, a specially appointed officer, who apparently devotes his whole time to the duties of the office. There are in the city 21 schools, comprising 42 departments and 7521 children, and the school medical officer is assisted by one school nurse, who is present at the examinations and visits the homes of the children to impress upon the parents the importance of acting upon the advice of the medical officer, and assists them in dealing with verminous conditions. Mr. Stirk thinks that the inspections during 1908 did not interfere with the grant-earning capacity of the schools except in cases where scholars were kept away from the schools by the parents in order to evade the examinations. He suggests, however, that the Board of Education should sanction the use of the central office for difficult cases which it is impracticable to examine at the schools, and that the time so occupied should be recognised as part of school attendance. In all 880 boys and 880 girls were examined in the schools and 40 children in their own homes, making a total of 1800, this number including 366 known to be defective by the teachers. Exclusive of the verminous, ill-clad, and ill-nourished, 743, or 42·2 per cent., were either physically or mentally defective. The time occupied in the examination of each child inclusive of completing the tabular records was approximately 12 minutes. The parents and the school nurse are informed of the defects in each case and the nurse repeatedly visits the home of the child until treatment is obtained or a refusal to obtain treatment given, but at the end of three months where no treatment has resulted the case comes up for re-consideration. As to the sources of treatment, all patients able to pay are referred to their private medical practitioners for medical, surgical, or dental assistance, but apart from these cases use is made of one or other of the charitable institutions with which Exeter is richly endowed—i.e., the Royal Devon and Exeter Hospital (200 beds), the West of England Eye Infirmary (80 beds), the Exeter Dispensary, and the Exeter Dental Hospital. As regards the Eye Infirmary a subscriber's recommendation is necessary before advice can be obtained and such recommendation does not include the cost of glasses, which varies from 2*s*. 6*d*. to 7*s*. 6*d*. per pair. Teeth are extracted at the Dental Hospital free of charge except where an anæsthetic is required, in which case a subscriber's letter is necessary. It appears that 65·1 per cent. of the children recommended for treatment have obtained it in a satisfactory fashion, but in 24 cases the parents declined to take any action. There were 35·2 per cent. of the girls in a verminous condition, and Mr. Stirk remarks that it is "a deplorable fact that the children of clean, respectable parents cannot be sent to the public elementary schools without the certainty of contracting at some time or other this disgusting and entirely preventable condition." He trusts that the Children Act which is now in force will be taken full advantage of in the case of those verminous children who are habitually neglected.

---

[1] In the return the augmentation is shown as 1·5 per cent. but this is evidently a printers' error.

[2] For a full account of the proposed drainage of Cairo and the various [illegible] we may refer to articles which have [illegible] il 3rd (p. 1014) and 24th (p. 1209) and [illegible] 1909.

Considerable difficulty is experienced in persuading the parents to take action with regard to their children's teeth, and Mr. Stirk points out that the number of recruits rejected by the military authorities on account of dental insufficiency in 1907 was nearly double that for any other defect. Although in 1906 the standard of "masticatory efficiency" was lowered and the dental treatment of recruits introduced, in 1907 no less than 48·17 per 1000 of the recruits were rejected. Of the total number of children 11·5 per cent. were habitual mouth-breathers, a circumstance generally due to enlarged tonsils, adenoids, nasal obstructions due to enlarged lower turbinate bones or deviations of the nasal septum. 6 per cent. of the children had enlarged tonsils and adenoids, and Mr. Stirk insists upon the uselessness of having adenoids removed unless their removal is followed by systematic and suitable breathing exercises. It is of interest to observe that of all the children examined only one showed definite pulmonary tuberculosis and only seven children showed other tuberculous lesions. But, as Mr. Stirk points out, the majority of children with tuberculous lesions do not attend school. An interesting section of the valuable report before us relates to the subject of the correlation of the school medical department with that of the medical officer of health. On every Friday the head teacher compiles a return of all children absent from school during the week from illness, together with the supposed cause of absence, and these returns, after tabulation of the children absent from infectious disease, are sent by the school medical officer to the medical officer of health, any doubtful case being visited by the health visitor to verify the supposed cause of illness. On the other hand, the medical officer of health notifies to the education authority all cases of notifiable infectious disease amongst school children or in houses in which school children reside, furnishing also the names of children who have been excluded from school on this account. Mr. Stirk is, he reports, preparing a "susceptibility table," which would show in the event of an outbreak of infectious disease the number of children who are unprotected in each school. So far it has been found that the children inspected have suffered from the common infectious diseases as follows: measles, 70 per cent.; whooping-cough, 49 per cent.; chicken-pox, 25 per cent.; diphtheria, 25 per cent.; and scarlet fever, 7 per cent.

The County of Surrey.—The Surrey county council has not apparently acted upon the spirit of the circulars of the Board of Education in so far as making its medical officer of health the superintending officer of school inspection is concerned, since Dr. T. Henry Jones reports directly to the Education Committee. It has, however, adopted what is described as a combined scheme whereby whole-time assistant medical officers have been appointed for the routine inspection of school children, while the services of the medical officers of health are "retained for general hygienic and emergency work in the schools of their own districts." For the purposes of the inspection of school children the administrative county has been divided into four parts and an assistant medical officer appointed for each district. Under the supervision of Dr. Jones, the chief medical officer, each assistant medical officer is responsible for the routine inspection in his district and resides at some convenient centre in such district. We notice that three of the four officers appointed possess the diploma of public health. Dr. Jones states that he is in constant communication with the medical officers of health upon all matters relating to the public health part of the work, and the medical supervision of the schools is so arranged as to avoid any overlapping of the function of the Education Authority and of the various sanitary authorities. The number of school children in the county area (exclusive of the boroughs) is 60,970, and the number allocated to each assistant medical officer varies from 9554 to 18,084. The total number of children at all ages actually inspected was 11,184, but the detailed report relates to the 10,281 routine inspections. Of these, 2017, or 19 6 per cent., were found to be suffering from defects calling for recommendations for treatment. But in addition to these recommendations the attention of teachers was called to 1027 children whose condition called for some modification of school work. The average time occupied by each inspection was under eight minutes, but it is not stated whether this time includes a record of the observations. Amongst other things, the children were inspected as regards their vaccination; 89·3 per cent had been vaccinated, 8 7 were unvaccinated, and as to 1·9 per cent. no information was forthcoming. Presumably if they had been vaccinated the cicatrices had faded. With respect to the treatment of diseased conditions, it was ascertained in February, 1909, that nothing had been done for 55·7 per cent., while in 28·3 per cent. treatment of a satisfactory character had been procured. Some of the parents did not, it seems, concur in the need for any treatment, it being said that "the teeth did not affect health" and as regards [illegible] journeys to hospital. In fact, this county forms an interesting contrast to the city of Exeter, where practically all the cases could receive treatment without expenditure or delay. In the Surrey report it is interesting to note that none of the parents referred to Poor-law medical treatment. If it was procured no mention is made of the fact. In connexion with this problem of treatment Dr. Jones thinks that there are but few districts in which arrangements might not be made for the treatment of the common defects by local medical men, and in his view many of the medical practitioners would treat really necessitous school children at reduced fees, which would amount to less than the cost of journeys to hospital. It seems, in fact, that experiments in the above sense are already in progress, and some of the local medical men have undertaken to estimate the visual defects of school children and obtain spectacles for such children at cost price from the makers at nominal inclusive fees, provided that the social circumstances of the cases are carefully investigated beforehand and that the children are recommended by the school managers. Some investigations were made in the Mitcham district into conditions of underfeeding among children, and Dr. Jones reports that the employment of the mothers has a marked effect upon the condition of their children. Such children, it is added, often enter school at five or six years of age untrained in proper habits and unable to speak properly.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS

In 76 of the largest English towns 8048 births and 4375 deaths were registered during the week ending May 29th. The annual rate of mortality in these towns, which had been equal to 13·7 and 14·7 per 1000 in the two preceding weeks, declined again to 13·9 in the week under notice.

During the first eight weeks of the current quarter the death-rate in these towns averaged 15·1 per 1000; the rate in London during the same period did not exceed 14·6. The lowest recorded annual death-rates in these towns last week were 6·0 in Leyton, 6·5 in Walthamstow, 6·7 in Smethwick, and 7·6 both in Hornsey and in Hastings; the rates in the other towns ranged upwards, however, to 20·7 in Rhondda, 21·1 in Oldham, 21·8 in Middlesbrough, and 23·1 in Warrington. In London the recorded death-rate during the week did not exceed 13·4 per 1000. The 4375 deaths from all causes in the 76 towns last week showed a decline of 275 from the number returned in the previous week, and included 417 which were referred to the principal epidemic diseases, against 395 and 413 in the two preceding weeks; of these 417 deaths, 178 resulted from measles, 102 from whooping-cough, 49 from diarrhœa, 39 from diphtheria, 33 from scarlet fever, and 16 from "fever" (principally enteric), but not one from small-pox. The 417 deaths from these epidemic diseases last week were equal to an annual rate of 1·3 per 1000, against 1·2 and 1·3 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Blackburn, Walthamstow, Leyton, Northampton, and in six other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·6 in West Ham, 3·4 in Norwich, 4·1 in Salford, and 9·5 in Wolverhampton. The fatal cases of measles in the 76 towns, which had steadily declined in the ten preceding weeks from 438 to 168, rose again in the week under notice to 178, and caused annual death-rates ranging upwards to 2·2 in Salford, 3·4 in Norwich, and 6·5 in Wolverhampton. The 102 deaths from whooping-cough showed a further slight increase upon the numbers returned in the two previous weeks, the highest death-rates from this disease last week being 1·2 in Wigan, 1·5 in Middlesbrough, and 2·1 in Swansea. The 49 deaths attributed to diarrhœa also showed a slight increase. Of the 39 deaths referred to diphtheria (a decline of 12 from the number in the previous week), four occurred in Birmingham and King's Norton, two in Salford and in Hull, and 19 in London and its suburban districts. The 33 fatal cases of scarlet fever exceeded the number in the previous week by one, and included five in Birmingham and Smethwick, seven in Manchester and Salford, three in Liverpool, and two in Sunderland. The 16 deaths referred to "fever" were fewer by four than the number returned in the previous week, but included three in Manchester and Salford. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2173 and 2234 at the end of the two preceding weeks, had further increased to 2254 on Saturday last; 335 new cases were admitted to these hospitals during last week, against 309, 313, and 348 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 212, 222, and 214 in the three preceding weeks, increased again to 225 in the week under notice and exceeded by 12 the corrected average number in the corresponding week of the five years 1904–08. The deaths in London referred directly to influenza, which had been 20 and 19 in the two preceding weeks, further declined last week to 17. The causes of 33, or 0·8 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during the week were again duly certified in Leeds, West Ham, Newcastle-on-Tyne, Bradford, Salford, Hull, and in 55 other smaller towns; the 33 uncertified causes of death included eight in Birmingham, six in Manchester, three in Liverpool and in Sheffield, and two in Sunderland and in South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 950 births and 596 deaths were registered in the week ending May 29th. The annual rate of mortality in these towns, which had been equal to 14·9 and 17·5 per 1000 in the two preceding weeks, declined again to 16·7 in the week under notice. During the first eight weeks of the current quarter the death-rate in these Scotch towns averaged 17·0 per 1000, while in the 76 large English towns the mean death-rate during the same period did not exceed 15·1. The death-rates last week in these Scotch towns ranged from 10·8 and 11·6 in Greenock and Leith to 18·2 in Paisley and 19·4 in Dundee. The 596 deaths from all causes in the eight towns showed a decline of 28 from the number returned in the previous week, and included 68 which were referred to the principal epidemic diseases, against 78, 47, and 76 in the three preceding weeks. These 68 deaths were equal to an annual rate of 1·9 per 1000, against 1·3 and 2·1 in the two preceding weeks; the mean death-rate last week from these principal epidemic diseases in the 76 large English towns did not exceed 1·3 per 1000. Of the 68 deaths from these epidemic diseases last week in the Scotch towns, 40 resulted from whooping-cough, 14 from diarrhœa, five from scarlet fever, five from diphtheria, three from measles, and one from "fever," but not one from small-pox. The fatal cases of whooping-cough in the eight towns, which had been 41, 17, and 38 in the three preceding weeks, rose again to 40 last week, of which 24 occurred in Glasgow, seven in Edinburgh, and three both in Dundee and in Greenock. The 14 deaths attributed to diarrhœa showed a further slight decline from the numbers in recent weeks, but included five in Glasgow, five in Dundee, and two both in Edinburgh and in Aberdeen. Four of the five fatal cases of scarlet fever were returned in Glasgow; and the five deaths from diphtheria included two in Glasgow and two in Paisley. All the three fatal cases of measles occurred in Paisley; and the death from "fever" (certified as cerebro-spinal meningitis) was registered in Edinburgh. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 88, 92, and 109 in the three preceding weeks, declined again last week to 94, but exceeded the number returned in the corresponding week of last year by nine. Seven deaths in the eight towns resulted from violence, of which five occurred in Glasgow and two in Dundee. The causes of 12, or 2·0 per cent., of the deaths in the eight towns last week were unspecified or uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 18·5 and 22·3 per 1000 in the two preceding weeks, declined again to 21·7 in the week ending May 29th. During the first eight weeks of the current quarter the death-rate in the city averaged 23·0 per 1000, whereas the mean rate during the same period did not exceed 14·6 in London and 16·6 in Edinburgh. The 166 deaths of Dublin residents from all causes during last week showed a decline of four from the high number in the previous week, and included 13 which were referred to the principal epidemic diseases, against 11 and nine in the two preceding weeks. These 13 deaths were equal to an annual rate of 1·7 per 1000, the death-rate from these principal epidemic diseases in the same week being 1·5 both in London and in Edinburgh. Of the 13 deaths from these epidemic diseases in Dublin last week, six resulted from whooping-cough, four from diphtheria, two from "fever," and one from diarrhœa, but not one either from measles, scarlet fever, or small-pox. The fatal cases both of whooping-cough and of diphtheria showed a marked increase upon recent weekly numbers. The 166 deaths registered last week included 32 of infants under one year of age and 47 of persons aged upwards of 60 years; both these numbers showed a slight decline from those in the previous week. Four inquest cases and six deaths from violence were registered last week, and 77, or 46·4 per cent., of the deaths occurred in public institutions. The causes of all but one of the 166 deaths registered last week in Dublin were duly certified; in London the causes of all but one of the 1240 registered deaths were also duly certified, while in Edinburgh the proportion of uncertified causes was equal to 3·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881:—Staff-Surgeon Robert Robertson Fasson has been allowed to withdraw from His Majesty's Naval Service, with a gratuity.

The following qualified candidates for the Naval Medical Service have been appointed Surgeons in His Majesty's

Fleet —Kenneth Hill Hole, Gilbert Francis Syms, Arthur Addison Sanders, Michael Paul Fitzgerald, John Hadwen, Harry Williams Nicholls, Raymond Paul Middleton Roberts, Alfred Graham Malcolm, Horace Charlton Devas, Henry Burns, Hugh Francis Briggs, Gordon Alexander Jackson, William Miller, James Stewart Orwin, and James Barnett (dated May 14th, 1909)

The following appointments are notified —Fleet Surgeons A G Andrews to the *Superb*, A M Page to the *Swiftsure*, J A Keogh to the *Jupiter*, J L Smith to the *Exmouth*, J E Coad to the *Nelson* G A Waters to the *Drake*, W E Marshall to the *Excellent*, additional for the *Revenge*, and T Austen to the *Achilles* Staff Surgeons R A Ross to the *Illustrious*, and J W W Stanton to Plymouth Hospital Surgeons B R Bickford to the *Superb*, P D M Campbell to the *Excellent*, additional for the *Grafton*, A R Fisher to the *Jupiter*, F G Hitch to the *Shannon*, and R L Jones to the *Exmouth*

ROYAL ARMY MEDICAL CORPS

Captain J W S Secombe has been appointed Officiating Sanitary Officer, 3rd (Lahore) Division, vice Captain J H Brunskill, proceeding on leave

TERRITORIAL FORCE

Royal Army Medical Corps

1st London (City of London) Field Ambulance Lieutenant Andrew Elliot, from the 2nd London (City of London) Field Ambulance, to be Lieutenant (dated March 4th 1909)

3rd South Midland Field Ambulance Charles Corfield to be Lieutenant (dated March 18th, 1909) Alfred Coleridge to be Lieutenant (dated March 23rd, 1909)

1st Welsh Field Ambulance Lieutenant Thomas Donovan to be Captain (dated Dec 12th, 1908)

1st London (City of London) General Hospital Officers whose services will be available on mobilisation Captain James Calvert to be Major (dated Feb 20th, 1909), and Captain William McAdam Eccles to be Major (dated March 13th, 1909)

1st Northern General Hospital The undermentioned to be officers whose services will be available on mobilisation (dated March 30th, 1909) To be Lieutenant Colonels David Drummond, Sir Thomas Oliver, George Walter Ridley and Albert Morton Martin To be Majors Henry Brunton Angus, Thomas Beattie, William Errington Hume, William George Richardson, William Drewett Arnison, John Dobson Wardale, and Robert Patton Ranken Lyle To be Captains Joseph William Leech, George Grey Turner, Horsley Drummond, Alfred Parkin George Hall, Thomas Moffatt Allison, Joseph Collingwood Stewart William Edward Moore Ede, Samuel Short Whillis Daniel Wells Patterson, Thomas Gowans Herbert James Slade Henry Herbert Markham William John Phillips William Seymour

For attachment to Units other than Medical Units —Frank John Hathaway (late Lieutenant, United Services College Cadet Corps) to be Lieutenant with precedence as from April 8th, 1907 (dated July 15th 1908)

VOLUNTEERS

Cadet Corps United Services College, Windsor Lieutenant Frank J Hathaway resigns his commission (dated July 15th, 1908)

THE GERMAN ARMY MEDICAL COLLEGE

The current issue of the *Broad Arrow* contains a brief but interesting note on the German Army Medical College, the senior course of which is not quite similar to our own "The course at the Kaiser Wilhelms Institut," says our contemporary, "is in reality that of a cadet school like the French school at Lyons The Germans have no 'Applikations Schule' like the 'Val de Grace' or the school at Vienna, so that there is no actual equivalent of our Royal Army Medical Corps The junior Stabsärzte and the senior subaltern medical officers must go through a post graduate course called the Fortbildungscursus or operations course They are placed on command by the War Office for this The course consists of attendance at the clinics of universities and larger hospitals Lieutenant Colonel W. S Macpherson, R.A M C, attached to the department of the Chief of the General Staff, in a note to his hand book says that recently the higher administrative officers have also been made to attend the operations course at the Kaiser Wilhelms Akademie He also states that recently an institute for post graduate study, the Kaiserin Augusta Haus, was opened in Berlin, and army medical officers may go through a post graduate course (three months) there Apart from this, scientific libraries for the education of army surgeons are established (usually) in head quarters garrison hospitals of army corps In the summer staff rides are organised, and in the winter months medical officers on the active staff are obliged to write essays on some special scientific work, the subject being set by the Director General Special facilities are given for post graduate study and war games also form a part of the educational studies of the medical officers

"Audi alteram partem"

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN

To the Editor of THE LANCET

SIR —Notwithstanding the letters appearing in your columns and your own remarks thereon, I have been surprised, in conversation and discussion with many members of our profession, to find how few are alive to the important —I would say momentous—issues which must of necessity be involved when putting into practice the Act of Parliament which gives the London County Council the right to procure medical aid for children educated in their schools For the moment the London County Council are not of one mind They are possibly embarrassed at the magnitude and delicacy of the task before them But whatever may be the decision of the Council, it behoves the whole profession to be on its guard and to watch the approach of what may prove to be of prime importance to every member of every branch of medicine and surgery

Should the Council by means of alluring offers of subsidy, seduce the managing committee of any hospital to treat their afflicted children, it must follow that both you and I contribute through our rates to supply this subsidy The unfortunate assistant physician or surgeon will have to submit to a double tax he will have to meet, in addition to his rates, a demand for extra time which he will be compelled to devote to the out patient department

Should our hospital authorities place themselves at the mercy of the London County Council in accepting payment, they must not be surprised at strict supervision—may be, interference—at the hands of those who will naturally wish to know how their patients are being cared for Much more might be said I prefer for the moment to press the main question, which appears to me to be of such importance that [illegible] eventually taken should be a concerted one and not [illegible] hospital board

Green street Park lane

DONALD W C HOOD

To the Editor of THE LANCET

SIR —The Education (Administrative Provisions) Act of 1907 authorises the local education authority, with the consent of the Central Government, to establish and maintain at the cost of the rates school hospitals with both in and out patient departments and country branches [1] I submit that in the interest of the patients this should be done, to establish only out patient departments for eye and ear cases is, owing to the inadequate support given to voluntary hospitals to lose a certain proportion of the chronic bone and other cases which under early and continuous treatment might be saved

Of the children of school age 86 per cent are in public elementary schools, 10 per cent in Poor law schools orphanages or ill and only 4 per cent are being educated at the cost of their parents, thus if school hospitals are established about 95 per cent of the children will be treated in them and only 5 per cent left to the open competition of the profession This would be a great, but, as I think, necessary evil, in order to minimise it as far as possible the following steps should be taken —1 The appointments should be made not by a subcommittee of the education committee, but by an electoral board on which the medical profession is represented. 2. No applicant should be prejudiced in his candidature because he does not intend to confine his private practice to the specialty of the appointment, or because he proposes to accept less than guinea fees. 3. That any qualified practitioner in the district may, under suitable safeguards, avail himself of the advantages of the clinical and pathological laboratories of the school hospital, both for the diagnosis and treatment of any school child he may have as a patient and for the purposes of research. In this connexion it must be remembered that the advances of medicine tend to make the investigation and treatment of disease more elaborate and the apparatus more costly; it is one thing to buy a stethoscope, another an x ray outfit. 4. That medical certificates given by an unattached practitioner should carry equal weight with one by an official, any difference of opinion that may arise being referred to an independent expert.

---

[1] THE LANCET Nov [illegible] 1907

I am, Sir, yours faithfully,

May 31st, 1909. J. S.

A PLEA FOR THE USE OF ANTI-DIPHTHERITIC SERUM.

To the Editor of THE LANCET.

SIR,—I read with much interest the paper by Dr. A. A. Warden in THE LANCET of May 15th on the use of antidiphtheritic serum in laryngitis, the sequence of measles, but I gather therefrom that when the serum was used diphtheria in reality existed. That this serum has a wider field of application than for the treatment of pure diphtheria.I am quite convinced, and I first arrived at this conclusion entirely through accidental circumstances. I now nearly always resort to it in cases of quinsy or bad scarlet fever throats in preference to the polyvalent serum.

I quote briefly the outline of four cases. I saw C. D. on Nov. 5th, 1906, at 9 A.M., with quinsy, soft palate very red and œdematous, with a patch of membrane on left tonsil He had been using hot inhalations of Friar's balsam but could not swallow. At 10.30 A M. I injected 4000 B.U., and at 10 P.M., when I again visited him, he could swallow easily; a swab was taken, with negative results; the case ran an ordinary course but the quinsy aborted. Mrs. X. was seen on Jan. 6th, 1907. She had quinsy. I injected per rectum 4000 B U., and 2000 B.U. the next day. In five days the quinsy had quite disappeared (aborted). This lady informed me that she had had three or four quinsies each year for the two previous years; she has had none since she was injected. A. and B., aged four and six years, sisters, were admitted into the infectious hospital with scarlet fever; rash was profuse on each, and bad throats. but B.'s looked suspiciously like diphtheria as well. I injected 4000 B.U. under scapula; swab was taken with negative result. B.'s throat was well in four days with no other treatment. A.'s throat was no better even on the ninth day, although treated with chlorine. E, aged 15 years, was seen on August 28th, 1908, with quinsy; she had had follicular tonsillitis five days. At 5 30 P M. I injected 4000 B.U. per rectum. In two days she was convalescent, the quinsy aborted, and two days after she was well and went to Cromer. I could quote two other cases of scarlatinal quinsy with like results. These are interesting facts and I am sure will prove worthy of consideration.

I am, Sir, yours faithfully,

FRANK ARGLES,

Medical Officer of Health to the Wanstead Urban
District Council and Fever Hospital.

Wanstead, N.E., May 27th, 1909.

THE EARLY RECOGNITION OF UTERINE CANCER.

To the Editor of THE LANCET.

SIR,—The recommendations of the Council of the British Medical Association, in regard to the early recognition of uterine cancer, which appeared in THE LANCET of May 15th, p. 1409, admirable in themselves as a form of post-graduate instruction for medical men and nurses, do not go to the root of the matter.

In cancer of the uterus, as in cancer of other parts of the body, the real difficulty is the bringing of the patient to the medical man while the disease is in an early stage and curable by operation. This bringing of the patient to the medical man cannot be effected by increasing the diagnostic powers of the latter, and increase of knowledge on the part of nurses can assist but slightly. It is the patients themselves who must be instructed in the importance of the elementary signs and symptoms of early cancer. The laity must be instructed by those who have the necessary knowledge. The possessors of this knowledge are the members of the medical profession, who must act as instructors. The contention that such instruction of the laity will generate a morbid fear of cancer is not a valid objection. Widespread "cancerophobia" has long been in existence, but in their present state of ignorance patients nearly always centre their fears on an affection because it is painful and which, consequently, is usually either not cancerous, or, if cancerous, cancer in an advanced and inoperable stage.

In its present form this existing dread of cancer hinders rather than assists in bringing the patient to the medical man while the disease is still curable. Instruction of the laity can hardly increase the existing dread of cancer, while it may be expected to transfer the fears of patients from the painful non-cancerous to the painless cancerous affections, which in many cases will be promptly brought to the notice of the medical man. For some years this instruction of the laity has been in force in portions of Europe and the United States of America, and the sooner a similar system is introduced into the British Isles the better for all concerned.

I am, Sir, yours faithfully,

Plymouth, May 23rd, 1909. C. HAMILTON WHITEFORD.

FERGUSSON *v.* MALVERN URBAN DISTRICT COUNCIL: APPEAL OF PLAINTIFF BEFORE HOUSE OF LORDS.

To the Editor of THE LANCET.

SIR,—I think it is desirable to prevent any misconception of the true state of facts that may arise from reading the letter of Dr. J. N. F. Fergusson which appeared in your issue of May 29th.

In the first place, I would point out that the Lord Chancellor distinctly said, "I must add that I think in this case that the decision of the Court of Law is strictly in accordance with justice between the parties." And the President of the Court of Appeal at the end of his judgment, which has been upheld by the House of Lords, said: "Just to sum this matter up. Here the plaintiff was not drawing the water by the pipes in question from his own land, he had by the findings no right whatever to draw this water from the defendants' land, he was in truth and in fact using it without any right to do so and without knowledge on the part of the defendants that he was doing so." The polluted water was a private supply and at the time leased to the Malvern council, and it has since been cut off from Dr. Fergusson's establishment by the owners. It is only right to add that this water was entirely apart from the town supply, and before it was diverted ran into the storm-water drains.

I am, Sir, yours faithfully,

FRANCIS WM. JOSHUA, L.R.C.P., L.R.C.S. Edin.

Great Malvern, May 31st, 1909.

FAVUS AND RINGWORM AMONG SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—In your columns recently a correspondent, writing over the signature M.D., sought information as to the treatment given in the London County Council's favus school, and inquires why that treatment cannot be given in cases of ringworm among children attending the Council's schools instead of the x ray treatment recommended by the committee. If your correspondent will refer to page 38 of the report of the London County Council medical officer (education) for the 21 months ended Dec. 31st last he will find full details of the treatment given in the favus school, which appears to consist of a combination of x ray treatment and the local application of a solution of cyllin.

I am, Sir, yours faithfully,

F.R C S.

May 27th, 1909.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol.

THE actual Charter arrived in Bristol last week, the King's seal having been affixed on May 24th. On Sunday, May 30th, reference was made to the foundation of the University from many pulpits. The total subscriptions to the University fund amounted to about £203,500, and the value of the existing buildings, &c., is estimated at about £55,000. The Blind Asylum premises and grounds are to pass into the University's possession for a sum of £27,500, and it is probable that some of the space thus provided will shortly be utilised for a new science wing to house the departments of chemistry and physiology. This will adjoin the existing premises. The purchase is one which adds not merely an excellent frontage but also a very considerable area of ground to the University. The Bill authorising a transfer of the property and liabilities of University College to the University of Bristol has been read a third time in the House of Lords. It is expected that the Lord Mayor will shortly be asked to convene a citizens' meeting for the purpose of raising a fund to supply the University with a permanent income of from £2000 to £3000 per annum. It is reckoned that it will need at least £28,000 a year; and the present available income amounts to about £26,000 only. The War Office has sanctioned the formation of an Officers' Training Corps in connexion with the University. This cannot, however, be started before October, but meanwhile names of students who wish to join are being collected. —The foundation of a chair of economic biology was under discussion at the annual meeting of the National Fruit and Cider Institute, in connexion with which the University College Department of Economic Biology has been making researches into cider growing.

Medical Inspection of School Children.

The education committee of the Bristol city council has issued its first report on the medical examination of school children, covering the last four months of 1908. Inspection is carried out by five part-time medical officers, to each of whom a section of the city is allotted. These officers occupied their first month (September, 1908) in a general inquiry into the under-feeding of school children, and issued a report on the strength of which the committee evolved a scheme of free meals for those who needed them. Routine inspection began in 1908, each officer visiting the schools in his district one by one on days appointed. The value of the work, which was carried out in each case in a room set apart for the purpose, was greatly enhanced by the presence of the head teachers of departments, whose personal knowledge of the children proved very helpful. In the three months (October to December) 3081 children were examined, and parents were advised to get treatment for their children in 1213 cases. Of these, 68 were notified unfit for school, 387 needed general medical treatment, 59 were suffering from neglect, 29 had contagious skin diseases, 331 had dirty heads, 206 were suffering from eye diseases and defects, and 241 from bad teeth. The inspection of each

oped,
An
its at

The Bristol Lunatic Asylum.

Dr. J. V. Blachford, medical superintendent of the Bristol City Asylum, reports the admission of 247 patients in 1908, 103 men and 144 women. 40 of these were boarders from the Essex County Asylum. During the year 84 patients were discharged as recovered and 140 died; in 123 of these a post-mortem examination was made. The average number of patients in residence per day was 928. The asylum farm and garden have provided all the vegetables required throughout the year, and there has been a plentiful supply of plants and flowers for indoor decoration from the greenhouse. New wards for male patients have been opened.

What is Successful Revaccination?

At a meeting of the Chipping Sodbury (Gloucestershire) board of guardians held recently a letter was read from the Local Government Board stating that one of the public vaccinators had complained of the guardians not having paid him for ten cases of revaccination which he had performed. He had marked the cases in his vaccination register as "four groups abortive." The public vaccinator asked the Local Government Board to define successful revaccination and contended that the ten cases had been successfully revaccinated, as they conformed to the type laid down by the Privy Council—viz., "no outer vesicles but merely papular elevations surrounded by areolæ." The clerk to the guardians said he had disallowed the fees owing to the words "abortive," which he considered was unsuccessful, but eventually it was decided that the fees should be paid.

Royal Institution of Cornwall.

At a meeting of the Royal Institution of Cornwall, held at Truro on May 25th, it was stated that the Prince of Wales had given 200 guineas to the fund for a new county museum building at Truro. His Royal Highness directed "that the donation should be made in memory of Sir Humphry Davy and Richard Trevithick, two great Cornishmen, who commenced their careers with few advantages, and left names which can never be forgotten."

The Handel Cossham Memorial Hospital, Kingswood.

A semi-official explanation of the circumstances which led to the closure of this hospital has appeared in the local papers. The estate, the proceeds of which have been spent on the hospital, is still in Chancery, and this has hampered the board of management to some extent. Unfortunately, also, there was a considerable difference between the estimated and the actual amounts required for the initial expenditure as well as for the annual upkeep, and the consequence is that many expenses were incurred which might have been avoided or at least diminished. In order to deal with this situation a partial closure of the hospital was decided upon, but this decision has been extended to a general closure, because the small-pox outbreak which occurred there recently has rendered a thorough disinfection necessary. Pending the decision of the Court of Chancery, therefore, the work of the hospital is suspended.

June 1st.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

ARRANGEMENTS for the visit of the King and Queen to the new buildings of the University are being developed as rapidly as possible and it is understood that a general plan has been formed, but the many important details upon which success must rest are yet under consideration. The general public, and especially those interested in the University, are anxious to know as soon as may be what the arrangements will be, but a little time must necessarily elapse before everything can be finally decided upon, and the University authorities will no doubt furnish full information at the earliest possible moment.

The Ingleby Lecture.

Sir Thomas Barlow delivered the first part of the Ingleby lecture for 1909 on May 27th in the medical theatre. He dealt in elaborate detail with the main features of Raynaud's disease and erythromelalgia, contrasting them and arriving at the conclusion that they are not the same disease in different forms.

The Meeting of the British Dental Association.

The medical part of the University was largely in the hands of the British Dental Association during the end of last week and the early part of the present week. This is the second time that the meeting has been held in Birmingham and on the last as on the first occasion it was extremely successful. Naturally most of the papers and discussions have been more or less interesting to medical men, but the discussion which most nearly touched the interests of the medical profession was that upon the General Anæsthetics Bill, which ended in a resolution, the association protesting "in a most emphatic manner against any legislation which would make it illegal for registered dentists to administer anæsthetics for dental operations."

Medical Inspection in Worcestershire.

"A recent meeting of the Worcestershire education com-
subcommittee, which recom-
salaries of the two assistant
medical officers and the appointment of an additional officer,

received a very unfavourable reception from some of the members of the committee. It can scarcely be contended that the salaries at present paid, £175 per year to each assistant, are sufficient, or that the suggested increase, to £225 rising to £250, is too much to pay for properly organised and properly carried out work. There is no doubt, however, that many people are beginning to wonder what the medical inspection scheme is going to lead to and how the expense is to be met, whilst in the particular instance under consideration some of the members of the committee were no doubt irritated by what must have seemed to them the strangely contradictory reports of the medical inspectors concerning the prevalence of pulmonary tuberculosis; one inspector reporting under the head of phthisis 0·8 per cent of defective children, and another 15·5 per cent., whilst no proof was furnished that either the lower or the higher estimate was correct. The desirability of recognising early stages of pulmonary tuberculosis is undoubted but the advisability of publishing unverified conclusions is doubtful.

Educational Standards and Inborn Incapacity.

At the last meeting of the Birmingham education committee an interesting discussion took place, originating in association with the statement that 25·7 per cent. of the children did not attain Standard VI. before leaving school, and with Mr. Cary Gilson's suggestion that it would be wise to provide a curriculum more suited to the requirements of the children who were not likely to reach the sixth standard. The suggestion was strongly objected to on the grounds that the children were not incapable of attaining the standard before the leaving age, but were prevented from attaining it by lack of proper school accommodation, migration of parents, sickness, and by the fact that many of them had to work before going to school and were too tired to learn. All these causes may be at work, and if carefully inquired into might serve to reduce the somewhat large percentage of those who seem to be incapable of attaining the much worshipped Standard VI., but the fact remains that many children, who cannot be classed as feeble-minded, are not capable of attaining the standard in the usual period. Many of our legislators apparently will not believe in the inborn incapability of some children. They are quick to recognise with regard to animals, and with regard to the men and women whom they utilise for business purposes, that some are more and some less capable, but when they have to deal with children they appear to think that every child is born with equal potentialities and is capable of being crammed with knowledge up to Standard VI. in a given time. It is a pity that many of those who occupy public positions with regard to education cannot be made to go through a well arranged course of study in biology. It might dispel some of their cherished ideas of natural equality under equal external conditions and induce them to cease, not only spending the people's money in trying to force the incapable to a height they cannot attain, but also to cease retarding the development of the better types by squandering what should be devoted to them upon the incapables. If medical men who know the truth would more frequently point out to the general public with whom they come in contact the fact that we are not born equally capable, and that it is the capable and not the incapable who should be fostered if the nation is to become stronger, the public might gradually be educated to recognise the folly of squandering its strength for the sake of maintaining and propagating weaklings, which seems to be the main object of many of the present-day sociologists.

The Birmingham Medical Benevolent Society.

At the annual meeting of the Birmingham Medical Benevolent Society Dr. Malet, the retiring President, was replaced by Sir Thomas Chavasse, and Dr. Simon was appointed President-elect. The directors reported that the funds of the society amounted to £16,060 14*s.* 6*d.*, of which £15,940 4*s.* 11*d.* were invested. During the past year two annuitants died and one was added to the list, the number being thus reduced to 25, and the total number of members at the end of the year was 390. This is a very small number out of a total of 4000 eligible medical men in the area covered by the society, and it is obvious either that the objects of the society or the means of attaining them do not appeal to the majority of medical men, or are not effectively brought to their notice. In a motion proposed by Dr. Thomas Wilson it was decided to admit lady practitioners to membership of the society.

The Monyhull Colony.

The Monyhull Colony for Epileptics and Feeble-minded was founded about 13 months ago with the object of furnishing the most favourable conditions for the epileptics and feeble-minded in the parishes of Birmingham, Aston, and King's Norton. It has not been long enough in existence to provide any very certain data with regard either to the cause of epilepsy or the most successful method of treating epileptics and the feeble-minded; therefore it is not surprising that the first annual report of the medical officer contains little but a record of the general improvement of the physical condition of the patients. It has been stated that the number of epileptic fits can be reduced by a "no salt" diet, and with the object of testing the statement 12 men and seven women have been placed upon such a diet, but Dr. B. F. Jordan, the visiting medical officer, is of the opinion that the experiment has not been continued long enough to justify the formation of a definite conclusion. It was noted, however, that some of the patients placed on the "no salt" diet developed a temporary dulness of manner. Dr. Jordan states that manual work, in the cases of the able-bodied patients, tends to reduce the number of fits, and he notes a marked tendency amongst the epileptics to sudden attacks of long-continued physical weakness appearing without adequate cause.

June 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Scottish Dinner of the Indian Medical Service.

THE fourth annual Scottish dinner of the Indian Medical Service was held in the Caledonian United Service Club, Edinburgh, on the evening of May 28th, under the presidency of Sir Alexander Christison, Bart., the oldest member of the service present. Sir Alexander Christison, it may be stated, not only served through the Mutiny, but was also attached to a field hospital during the first Burmese war, and was then associated with the late Sir Joseph Fayrer. The other members of the service who attended the dinner were: Surgeon-General G. Bidie, C.I.E., Surgeon-Major-General P. S. Turnbull, K.H.S., Surgeon-General D. Sinclair, C.S.I., and Surgeon-General G. W. R. Hay; Colonel A. Stephen and Colonel W. P. Warburton, C.S.I.; Brigade-Surgeon-Lieutenant-Colonel J. Arnott, Brigade-Surgeon-Lieutenant-Colonel G. G. McLaren, and Brigade-Surgeon Robb; Lieutenant-Colonel Downie, Lieutenant-Colonel W. B. Bannerman, Lieutenant-Colonel G. J. H. Bell, Lieutenant-Colonel Smith, and Lieutenant-Colonel Lamont; Major C. J. Robertson-Milne; Captain Harvey, Captain G. H. Stewart, Captain Husband, Captain Masson, Captain Roberts, Captain Macrae, Captain Morison, Captain Kirkwood, and Captain Tarr. Apologies for inability to attend were received from Surgeon-General W. Watson, Surgeon-General Pinkerton, Lieutenant-Colonel F. Wyville Thomson, and Captain Fleming. The guests present were Sir J. Halliday Croom, Dr. W. Allan Jamieson, Mr. J. M. Cotterill, Colonel Corker, R.A.M.C., Dr. P. McBride, Dr. F. W. N. Haultain, and Lieutenant Turnbull of the 23rd Pioneers. A most delightful evening was spent, and brother officers who had not seen each other for many years—in one instance no fewer than 41—enjoyed the pleasure of meeting again and recounting the incidents of the intervals. After the usual loyal toasts had been honoured, Sir Alexander Christison, in a speech of great feeling, proposed the continuous prosperity of the Indian Medical Service. He alluded particularly to the recent death of Assistant-Surgeon W. W. Ireland, I.M.S., whose presence at the dinner in the previous year when he detailed the pathetic story of his all too brief career in the Service, will never be forgotten by those who were present. Dr. Ireland had actually signified his intention of being present on this occasion, and the speaker suggested that on behalf of the officers attending the dinner he should write to the family of the late Dr. Ireland expressing sympathy with them in their sudden bereavement. Then, after referring suitably to recent changes in the service he concluded by expressing the great pleasure he had experienced that evening in meeting so many of the younger members of the service. Other toasts followed. Surgeon-General Sinclair proposed that of the "Royal Army Medical Corps," with which the Indian service is so closely associated in India, and Colonel Corker in acknowledging the toast referred to the many kindnesses he had received from officers of the Indian Service during the earlier years of his own career. Surgeon-General Hay proposed the "Royal Colleges of Physicians and Surgeons," to which the Presidents, Dr. Jamieson and Mr. Cotterill, replied in suitable terms, the latter alluding particularly to the revised standard of the Fellowship and its utility to members of the Service. Colonel Warburton, in conclusion, proposed the health of the Chairman, which was drunk with acclamation, as was that of Brigade-Surgeon-Lieutenant-Colonel Arnott, who had organised the dinner.

The Association for the Registration of Nurses in Scotland.

The executive committee of the Association for the Registration of Nurses in Scotland, at a meeting held in Edinburgh recently, passed a resolution expressing its satisfaction that the Prime Minister was unable to assent to the proposals of the deputation which waited on him on May 13th. This association (which represents, with a few exceptions, the opinion of the medical and nursing profession in Scotland) trusts that it will be afforded an opportunity of placing its views before any committee of the House of Commons that may be appointed to deal with this important subject. Although the association objects to both of the two Registration Bills already proposed the Scottish committee sees no reason why a Bill for the Registration of Nurses should not be introduced which would be satisfactory to England, Scotland, and Ireland, arranging [illegible] country, just as is done under the Medical Act (1858) and its [illegible] The views held by this asso[illegible] the recommendations of the [illegible] ted to Parliament in 1905 on the question of State Registration of Nurses. The executive committee instructed the honorary secretary to convey this resolution to the Prime Minister.

Forfarshire School Medical Officer.

At a [illegible] county [illegible] appoint[illegible] Forfarsh[illegible] examination and supervision of school children in the county (excluding Dundee) under the Education Act (Scotland), 1908, was discussed. A memorandum as to the proposal by the Secondary Education Committee of Forfarshire set forth that this committee had resolved that the area of the com[illegible] that, provided the county council agreed to pay one half of [illegible] such expenses; and (2) that the salary of the school medical officer should be £200 per annum, free of all expenses. After discussion it was unanimously agreed that permission be granted to the Secondary Education Committee to appoint the *county medical officer as* school medical *officer on condition* that the proposed scheme be submitted to, and approved by, the public health committee, as enlarged to include the whole county council, and, further, that an allowance of £50 per annum be granted to the county medical officer, out of which the county medical officer shall meet all expenses in connexion with his work as county medical officer, and that he shall give up all right to consulting practice, the whole matter to be subject to the approval of the Local Government Board.

Peterhead Doctor's Action.

In the Aberdeen small debt court on May 27th Sheriff Laing decided on a case of considerable importance to the medical profession. Some time ago some workmen engaged at Peterhead in breaking up a wreck met with some accidents. They were in the employment of Mr. Baird, Aberdeen, and on the accidents happening the foreman called in Dr. Gillespie, giving Mr. Baird's name. The injuries being very serious the medical attendance was long, and on the account being rendered to Mr. Baird payment was refused on the ground that he had not employed any medical man and that the foreman had not his authority for doing so. Proof was led at length, and the Sheriff in giving judgment said: "It is common ground that defender would be liable for this doctor's account if he instructed him either expressly or by implication. There is no suggestion that the master instructed the doctor. The case for the pursuer is that he undertook liability by implication. I hold that the pursuer has proved an implied undertaking. Each of the employees, it is of interest to note, was taken to the same doctor by the same men and it is proved to my satisfaction that they said defender would see to the payment of doctors' charges. Even this, however, would not be sufficient, but I must hold it proved that the foreman reported the accidents immediately, and the fact that Dr. Gillespie had been called in to the defender, who did nothing to repudiate liability then. Not only so, but when he met the doctor some little time after he said nothing then as to non-payment. This is, I think, sufficient to infer adoption of Dr. Gillespie's employment and sufficient for the decision of the case in pursuer's favour."

Care of Consumptives: Proposed New Dundee Municipal Venture.

The subject of the care of consumptives by the municipality was introduced in a new form at a meeting of the public health committee on May 25th. It had been agreed that certain cases should be sent to the sanatorium at the expense of the municipality, but this scheme was dead and the question now was, What was to be done? The alternative to doing nothing was to take up a lesser scheme It was then moved and seconded that a subcommittee be appointed to report. The suggestion that this motion and two others dealing with compulsory notification of tuberculosis and an isolation block or hospital for advanced cases be sent to the same committee found no support.

June 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Primary Schools.

A DEPUTATION from the Women's National Health Association of Ireland waited on the Chief Secretary for Ireland at Dublin Castle on May 24th. The Countess of Aberdeen, in speaking on behalf of the mothers of Ireland, said they desired to urge upon the Government the necessity for provision for heating, cleaning, ventilating, and general sanitation of the primary school buildings in Ireland. The present lack of such provision constituted a grave danger to the health of the children. Several ladies *having spoken, Mr. Birrell admitted at once that the state of* too many of the schools was very bad. There was no educational rate in Ireland, and although the National Board of Education in Ireland year after year asked for a sum of £40,000 to provide proper school accommodation for Irish children, the Treasury refused on the ground that it was an unreasonable demand, as there being no school-rate in Ireland, the least the people could do was to see that the schools were in a proper condition to receive the children. Mr. Birrell said he would *never assent to compelling* parents to send their children to school in the unsatisfactory condition in which so many of the schools are. At present there was a Bill before Parliament to halve this cost of £40,000 and to provide that if the local authority levies the rate sufficient to meet half the expense the Treasury should pay the other half. Now, provided the people of Ireland unitedly supported the Bill before Parliament referred to by him and brought pressure on the managers of *schools to raise half the sum,* Mr. Birrell said he hoped to be able to overcome the objection of the Treasury, but otherwise he said they would hear no more of the Bill. Mr. Birrell said he had seen

CONSTANTINOPLE.

Infectious Diseases at the Sites of the Recent Massacres.

FROM different parts of Asia Minor where the recent terrible massacres took place comes the alarming news of the outbreak and spread of different infectious diseases amongst the destitute victims. Information received from Erzerum and other provinces of Armenia gives a very sad picture of the present state of affairs, and according to the *Levant Herald*, with summer coming the problem in Adana is appalling. The refugees are for the most part gathered in camps outside the city, but there are 32 sections in the encampment, measles and other contagious diseases being strictly segregated. This arduous task has been accomplished by Commander Carver, H.M.S. *Swiftsure*, and the Rev. Stephen Van R. Trowbridge of Aintab. As rapidly as possible tents are being constructed and blankets and bedding distributed. Supplies are coming in slowly, however, and there are 20,000 people in the big camp. Fresh cases of wounds are brought in continually from the villages, most of them being in a state of hopeless gangrene. There is great and urgent need of more surgeons and nurses. Beirut, Aintab, Marash, and Smyrna have sent help to supply this need, but with so many to look after, unless a larger skilled staff is forthcoming, numbers are bound to perish from the physical impossibility of receiving attention from the present workers. Measles has proved as deadly as small-pox, for the children being in the open air and largely without bedding have contracted pneumonia and have died by the score. Almost all babies born since the massacres started are dead. Dysentery is rife throughout the camp. The central authorities in Constantinople, as well as the Armenian Committee and other charitable organisations, have sent money and medical help, but this does not seem sufficient to meet the urgent necessities of the case. Help is also coming from the United States.

The Sultan Visits the Wounded in the Hospitals.

The new Padishah has given another proof of his sympathetic care for his subjects. On May 24th he paid a visit to the extensive children's hospital of Shishli, where a large number of wounded officers and men are being treated. The Sultan was accompanied by the Commander-in-Chief, General Mahmoud Shevket Pasha, the liberator of the metropolis, and was received by the director of the hospital, Dr. Ibrahim Pasha, and the chief medical officer, Haireddin Bey. Six wounded officers were each presented with a gold watch by the Sultan, and 60 soldiers each with a silver one. He visited every section of the hospital and spoke kind words of praise and encouragement and eulogy to the wounded. The Sultan remained among the wounded for about an hour. He visited also other hospitals and was everywhere cheered enthusiastically by crowds of patriotic people.

The Municipal Health Service.

The following salaries have been fixed for the medical officers of the municipal service: 3000 piastres per month (£1 equals 120 piastres) for the chief of the sanitary staff; 2000 for the next in rank; 2000 for the director of the service of disinfection, and 2000 for each chemist and bacteriologist. The minor officers will receive 500 piastres. The General Council of the municipality of the city has decided to contract a loan of 1,000,000 Turkish liras to be used for the embellishment of the metropolis.

May 28th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending April 24th show 4007 deaths, compared with 4594 in the week preceding. Bombay Presidency reports 762, Bengal 215, the United Provinces 501, the Punjab 2165, Burma 99, the Central Provinces 58, and Rajputana 177.

Cholera at Ujjain.

The city of Ujjain and the adjacent *mela* camps have bee centres of cholera in epidemic form recently, from 10 to 1 cases having been registered daily. The mortality during th weeks ending April 24th has, however, been steadily on th decrease, and there have been no further attacks sinc then. It may therefore be hoped that the disease is prac tically stamped out. This is due to the energy displayed b Captain Koksingh Subha Sahib of Malwa, who deserve special praise, with the hearty coöperation of the medica staff and police, the latter ably controlled by Mr. Phatak the district medical officer.

Tuberculous Disease in Calcutta.

The *Indian Medical Gazette*, summing up a series o papers read at the Medical Section of the Asiatic Society of Bengal, arrives at some very remarkable conclusions with reference to the prevalence of tuberculous disease i Calcutta. Lieutenant-Colonel G. F. A. Harris, I.M.S, reports that one-tenth of all the cases admitted to the General Hospital during the two years of his residence had been tuberculous. Major Leonard Rogers, I.M.S, in an analysis of post-mortem records, proves that 25 per cent. of all the bodies examined show traces of tuberculous disease, while in 17 per cent. it is the actual cause of death. Colonel H. W. Pilgrim, I.M.S., also bears testimony to the extremely common occurrence of tuberculous lesions, and considers that the origin and spread of the disease are largely due to preventable causes. Thus tubercle is a greater danger to life in this part of India than any of the purely tropical diseases. There is also practical unanimity among the medical profession in India that properly equipped sanatoriums furnish the only efficient means of treatment, but there is a good deal of difference of opinion regarding the most suitable site. The civil surgeon of Darjeeling reports against that station: living is too dear, and phthisis is very prevalent amongst the resident population, who are much over-crowded during the season. He thinks Kalimpong would be more suitable. The civil surgeon of Hazaribagh and the Rev. Dr. J. G. F. Hearn, a medical missionary there, give that place a qualified recommendation. The station, however, is difficult of access, and Indians find the cold nights in December and January very trying. Dr. Hearn suggests Puri. No explanation is offered of the fact that while Europeans and Hindus suffer in an equal degree, the liability is decidedly the greatest amongst the Mahomedans.

New Small-pox Hospital for Simla.

The new small-pox hospital for native patients, on the spur below the Mahomedan cemetery at Boileaugunge, is nearly completed, and it might be well for the municipality to consider whether a hospital of this kind should not be devoted to infectious cases generally and not be reserved merely for one specific disease. Small-pox appears in Simla spasmodically and at irregular intervals, and when it is non-existent the hospital lies empty and useless. It must be admitted that cases of small-pox and other infectious diseases cannot very well be treated in the same building, but this difficulty might be overcome by the erection in the vicinity of the new hospital of corrugated iron huts which are easily disinfected. These would accommodate small-pox patients, leaving the main building for infectious cases generally. The old hospital close to the Church of England cemetery will shortly be demolished, and an unpleasant feature will thus be removed from what should be an open locality. The dismantling of the building should be carried out during the rains, when the danger from dust-infection can be practically eliminated. There is happily no chance just at present of an epidemic of small-pox in Simla. It was feared that, with the move of the Government offices from Calcutta, infection might be carried into the summer capital, but only three cases have been detected during April. Every precaution was taken by the municipal committee, and the inspection of railway passengers at Tara Devi station is still a very close one. There are, of course, a number of persons who come by road, but these are mostly from the Punjab, in which province the only epidemic disease at present is plague. The bazaar population of Simla is closely watched over by the medical officers of health, and any outbreak of small-pox would be at once known. Visitors therefore need not be under any apprehension that the disease is likely to be prevalent there this summer.

May 8th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Vital Statistics.

THE estimated population of New South Wales at the end of 1908 was 1,605,000. This shows an increase of 31,785 during the year, and of these 26,345 were due to an excess of births over deaths during the period. The number of marriages was 12,642, equal to 7·96 per 1000, which is the highest rate for 21 years. The births totalled 42,525, equal to 26 77 per 1000 of population, and were in the proportion of 104 males to 100 females [illegible] registered, equal to a rate of [illegible] numbered 16,090, equal to [illegible] cent. below the mean of t[illegible] mortality figure works out at 76 per 1000 births for the whole State.

Socialistic Ideas.

At the annual conference of the Victorian Political Labour Council the following resolutions were agreed to:—

[illegible] such as hospitals and asylums.

Resolutions of this description may not have much immediate practical importance, but they show the trend of opinion amongst the advanced Labour party on matters that will one day affect the medical profession throughout Australia.

Melbourne Dust.

The reputation of Melbourne for dust is well maintained by the disinclination of the city council to approach the problem in a systematic manner. Mr. Hunt, the Commonwealth meteorologist, has made some observations with Dr. Aitken's "dust counter." The highest count in the city was 773,000 particles per cubic centimetre of air. Dust was much more prevalent in the early morning than at any other period of the day, a fact probably accounted for by the absence of water-carts and the early street cleaning operations. The suburban air was found to be ten times purer than that of the city at a distance of some four miles from the centre.

Meat and Milk Supervision.

Professor Gilruth, who has just been appointed to the new chair of Veterinary Science in the University of Melbourne, has been interviewed on the methods of handling meat and milk. He is of opinion that Victoria is ahead of New [illegible] duty being [illegible] He does not [illegible] its digesti- [illegible] pervision of meat is done by the Agricultural Department, which he considers preferable to the Victorian system, the latter being in the hands of the Board of Public Health. In New Zealand all towns of 2000 inhabitants are compelled to erect public abattoirs.

Plague in Australia.

The reappearance of plague in Sydney is causing grave anxiety to the public health officials. Dr. J. Ashburton Thompson, the President of the Board of Health, has addressed through the daily press an earnest appeal to householders and city firms to assist the Board in providing and maintaining rat-proof defences for all dwellings and places of business The plague-infected area continues slowly but surely to extend, though the Darling harbour frontage appears still to be the centre from which infection spreads. Since March 7th 17 cases have been reported, of which five were fatal. Three cases of plague have occurred in Adelaide, two of which were fatal.

Health Officers.

The Victorian branch of the British Medical Association has lately been considering the unsatisfactory position of municipal sanitation, particularly in country towns. The position of health officer to country municipalities is in few instances more than a nominal appointment. The health officer is offered a few pounds per annum and is expected to do as little as possible except when specially requested. The majority of medical men holding such positions feel that it is impossible to carry out the duties adequately, and an agitation for the appointment of whole-time health officers has been initiated by the Ballarat division of the association. After a good deal of discussion it has been resolved to request the Government to appoint six extra assistant medical officers to the Board of Public Health, who would devote their whole time to the office and be allotted to country districts in which they could assist the local health officers in carrying out the requisite supervision.

Queensland Public Health.

Dr. B. Burnett Ham has issued a report dealing with public health matters in Queensland for the year ending December, 1908. The birth rate was 26·87 per 1000 and the death-rate 10·35. Infant mortality rate was 77·2 per 1000 births, diarrhœa being disastrously responsible for deaths among infants. Plague reappeared for the ninth year in succession, the total number of cases between July, 1907, and December, 1908, being 31, of whom two died. The corrected death-rate from plague for white population was 61·5 per cent. On June 30th, 1908, 65 persons (of whom 16 were whites) remained under detention for leprosy. A number of experiments were conducted with anti-plague serum from the Lister Institute. Guinea-pigs were inoculated with virulent plague bacilli and injected either before, simultaneously, or after with varying quantities (4 to 20 cubic centimetres) of serum. The serum was shown to possess very decided protective and even curative properties.

Personal.

Dr. R. J. Bull, the director of the bacteriological laboratory of the Melbourne University, has left for a holiday trip to Europe in the P. and O. steamer *Marmora*. By the same steamer Dr. T. Garnet Leary also set out on a visit to the old country, and prior to his departure was the recipient of a presentation from the residents of Sandringham, a suburb in which he has practised for some years.

New Melbourne Hospital.

At the last committee meeting of the Melbourne Hospital the question was raised as to whether the new building should be planned to provide for 300 or 400 beds The estimated cost of a building to allow for 400 beds was £154,000. The chairman and others feared, not the constructional outlay, but the added maintenance, as it has been very difficult to make ends meet with the present number of beds, which is barely 300. The medical staff strongly urge the increased accommodation.

April 27th.

Obituary.

WILLIAM W. IRELAND, M.D. EDIN.

THE late Dr. W. W. Ireland, whose death occurred rather suddenly at Musselburgh on May 17th, was born in Edinburgh in 1832 and was educated at the High School and University there, graduating as M.D. in 1855. He was a lineal descendant of John Knox through Mrs. Welsh, the great Reformer's daughter. Having studied in Paris and served a[illegible] Infirmary he became surgeon [illegible] shortly afterwards was sen[illegible] formed one of the major o[illegible] the siege he saw Lord Roberts (then Lieutenant) wounded and attended him on that occasion, while he himself after seven months of being almost continuously under fire was severely wounded, losing an eye. The bullet passed from the left orbit under the base of the skull, while he was further wounded in the shoulder. After a couple of years' stay in the hills, during which time he was compiling material for his "Siege of Delhi," the severity of his wounds compelled him to retire from active service with a grant of a special pension. A further period of convalescence spent on the continent after leaving India was utilised in writing "Studies of a Wandering Observer" and a novel "Randolph Methyl," a story of Anglo-Indian life.

Having by this time become attracted to the mental department of medicine, Dr. Ireland on his return home was appointed medical superintendent of the Scottish National Institute for Imbeciles at Larbert, where he remained for ten years, and the outcome of his work there was the classic

"Ireland on Idiocy and Imbecility," which soon became the standard work on the subject, and which was afterwards expanded into "The Mental Affections of Children." By this time his devotion to the study of medico-psychological subjects had become fully established, his practical knowledge of French, German, Italian, Spanish, Norse, and Hindustani serving in good stead in translating matter for epitomes and reviews of current literature on mental subjects.

In 1880 Dr. Ireland started a private home for the treatment of cases of arrested mental development, first at Stirling and later at Prestonpans and Polton; he conducted these institutions with much success for a number of years. His last years were spent in nominal retirement at Musselburgh, but he still continued an active worker on the literary staff of the *Journal of Mental Science* and was a frequent contributor to THE LANCET and other medical papers and to the more thoughtful section of the general press. Dr. Ireland's most original work was the application of medico-psychological knowledge and studies in heredity to the explanation of the lives and conduct of many great men, and he has illustrated his theories in the case of Swedenborg, Caligula, Nero, and the Russian and other rulers in his "Blot on the Brain" and "Through the Ivory Gate." This important department of history and biography had been much neglected by historians, though it has since received some attention. Dr. Ireland was an ardent student of history, particularly of the times of the Commonwealth, as is illustrated in his "Life of Sir Henry Vane." In 1905 Dr. Ireland was the recipient of an illuminated address and other marks of appreciation, the function taking place in the hall of the Royal College of Physicians in Edinburgh, the President being in the chair, while Dr. T. S. Clouston in an appropriate speech made the presentation.

Dr. Ireland was a man of striking individuality. Tall, erect, of fine physical proportions, well-shaped head, and calm and kindly visage, his appearance commanded attention, and as a figure at the meetings of the various societies where he often spoke his personality will not soon be forgotten. He was an independent thinker on all the subjects he took up and was not easily moved when he had formed his conclusions, and was sceptical as to new views when not backed by what he considered proper proof. Without exaggeration one might say that his knowledge was encyclopædic, while his industry was immense. He was kindly and humorous, and few of his friends will forget his merry laugh, while it was his delight to help those of his brethren requiring literary aid. A list of Dr. Ireland's works forms quite a catalogue. He was a member of various societies in his specialty of mental disease and corresponding member of various foreign societies, and he also took an interest in local and political matters, being chairman of the Prestonpans branch of the Unionist Association for some years. Dr. Ireland is survived by his elder son, Dr. Thomas Ireland, recently retired from the West Indian Medical Service, and a daughter.

CHARLOTTE LOUISA ELLABY, M.D. PARIS, L.S.A.

Dr. Charlotte Louisa Ellaby, who died on May 14th at her house in Harley-street at the age of 55 years, was the youngest daughter of the late Rev. J. W. Ellaby of Woodstone, Peterborough. She graduated in medicine in Paris in 1884, embodying in her thesis the fruits of research work in ophthalmology undertaken while she was a student. In the autumn of that year, on the recommendation of Mrs. Garrett Anderson, M.D., she went out to Bombay to join Dr. Edith Pechey, first as physician at a temporary hospital and afterwards as second physician to the Cama Hospital, a Government hospital for women and children. Here Miss Ellaby worked most successfully, not only in the special eye department which she inaugurated, but also in a very large out-patient department and an increasing private practice. After some years' work in India, desiring to devote herself entirely to ophthalmology, she resigned her appointments and returned to England. She then passed the examination of the Society of Apothecaries (which had recently been reopened to women) in order to have a registrable British qualification.

In 1890 Miss Ellaby was invited by the committee of the New Hospital for Women to organise an eye department in connexion with the hospital, and was appointed its first ophthalmic surgeon. Here she worked happily and successfully until failing health, fought with the utmost courage, compelled her resignation three years ago. In the winter of 1894-95 Miss Ellaby returned to India for a few weeks, her services having been specially requisitioned to perform a double cataract operation upon the Rani of Jamnagar. The operations were successful, but it was partly to this visit to India that Miss Ellaby attributed her subsequent ill-health. At the time of her death she was consulting ophthalmic surgeon to the New Hospital for Women, lecturer on ophthalmic surgery to the London School of Medicine for Women, and was also a Member of the Faculty of Medicine of the University of London. Miss Ellaby had the true scientific spirit, although her literary contributions to scientific journals were few; they included papers on "L'Action de la Strychnine et du Courant Constant sur l'Œil Normal," and on a series of cases of Retinitis observed in the wards of the New Hospital and elsewhere.

CHARLES MARSHALL KEMPE, M.R.C.S. ENG., L.S.A.

THE death occurred at Shoreham, Sussex, on May 23rd of Mr. Charles Marshall Kempe, who in the summer of last year retired from practice and the position, among many others, of medical officer of health for the urban district of Shoreham, an office which he had held for no fewer than 35 years. Educated for the medical profession, Mr. Kempe took the diplomas of M.R.C.S. in 1861 and L.S.A. two years later. He came from Cornwall to Sussex, and settling at Shoreham was appointed to a number of posts, for besides the medical officership already mentioned he held appointments in connexion with the Poor-law, the railway, and the port of Shoreham. In addition he had an extensive private practice, so that his record of professional service was a considerable one. It was a wrench to him to give up the many positions he had held so long, but, unfortunately, he had not of late enjoyed the best of health. The urban council and the local court of Foresters placed on record in illuminated addresses their testimony of the manner in which Mr. Kempe had always discharged his duties, and it was extremely gratifying to him to know that in April last the ratepayers of Shoreham elected him to a seat on the urban council, the body which he had so faithfully served as medical officer. He was a prominent Freemason, a past master of the local lodge, and founder of another lodge; while at the time of his death he was chairman of the board of managers of the Shoreham council school. He was the author of "The General Practitioner's Visiting List, Journal, Almanack, and Memorandum Book." Mr. Kempe was 69 years of age. His body was interred in Shoreham cemetery on May 26th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Theodor Wilhelm Engelmann, who had only recently retired from the chair of physiology. He was born at Leipsic in 1843 and studied in Jena, Leipsic, Heidelberg, and Göttingen. He then went to Utrecht as assistant to Professor Donders, whom he succeeded in 1889 as professor of physiology, remaining in that post until 1897, when he succeeded to Professor du Bois-Reymond's chair in Berlin. He has edited the *Archiv für Physiologie* for the last ten years. His own original papers include a great variety of subjects—e.g., the Origin of Muscular Force, the Colouring of Plants, the Structure of the Cornea, the Action of Light on the Retina, and the Physiology of the Heart.—Dr. Ferdinand Kornfeld of Vienna, whose name is well known in connexion with researches on the urinary organs.—Dr. Yêvetski, professor of ophthalmology in the University of Yurieff (Dorpat).

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill will shortly publish the following works. A new edition of "Minor Surgery and Bandaging," revised by Mr. Bilton Pollard, surgeon to University College Hospital. The first edition of this work, by Mr. Christopher Heath, was issued 48 years ago. The present (fourteenth) edition has been enlarged by nearly 100 pages and contains many new figures and a frontispiece of a surgeon in aseptic operating costume. "An Atlas of Dental Extractions, with Notes on the Causes and Relief of Dental Pain," by Mr. C. E. Wallis, assistant dental surgeon, King's College Hospital. The text will be supplemented with a series of illustrative plates.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following degrees were conferred on May 27th:—

M.D.—R. E. French, King's; J. C. L. Roberts, Clare; and F. W. M. Palmer, Jesus.
M.B., B.C.—F. C. Trapnell, King's; and J. W. B. Bean, H. Selwyn.
M.B.—N. Maclaren, Trinity; F. Worthington, St. John's; G. H. Davy, Gonville and Caius.

UNIVERSITY OF LONDON.—At examinations held in May for the M.B., B.S. degree the following candidates were successful:—

[illegible] Sydney Furness, University College Hospital; Colin James Galbraith, King's College Hospital; Horace Gooch, London Hospital; Alexander Edward Gow, St. Bartholomew's Hospital; Frederick Whewell Hogarth, Guy's Hospital; Edward Ratcliffe Holborow, University College, Bristol; Maurice James [illegible] John Edward Scudamore, [illegible] ndon (Royal Free Hospital) [illegible] Stocks, Victoria University [illegible] Tolhurst, Guy's Hospital, [illegible] w's Hospital; James Owen [illegible] Herbert George Willis, [illegible] Wood, Guy's Hospital.

* Distinguished in Medicine † Distinguished in Pathology.
‡ *Distinguished in Forensic Medicine and Hygiene.*
§ Distinguished in Surgery.

The following candidates have passed in one of the two groups of subjects:—

[illegible]

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Georg Nicolai, *privat-docent* of Physiology, has been granted the title of Professor.—*Bonn:* Dr. Paul Krause of Jena has been appointed Extraordinary Professor of Medicine.—*Caen:* Dr. Osmont has been appointed to the chair of Extraordinary Pathology and Operative Medicine.—*Clausenburg:* Dr. Nikolaus Jancsó has been appointed Extraordinary Professor of Clinical Diagnosis.—*Halle:* Dr. Rudolf Disselhorst, Director of the Anatomical and Physiological Institute, who has hitherto only held the position of Extraordinary Professor, has been promoted to a full Professorship.—*Marburg:* Dr. Paul Sittler has been recognised as *privat-docent* of Children's Diseases.—*Munich:* Dr. A. Hasselwander has been recognised as *privat-docent* of Anatomy.—*Munster:* This University, which has hitherto only possessed a partial medical school, is now about to be provided with a complete medical faculty.—*Toulouse:* Dr. Soulié, *agrégé*, has been appointed Assistant Professor of [illegible] *agrégé*, Assistant Pro- [illegible] Assistant Professor of [illegible].—*Vienna:* Dr. Karl Schwartz has been recognised as *privat-docent* of Physiology.—*Würzburg:* Dr. Hotz, Assistant in the Surgical Clinic, has been recognised as *privat-docent* of Surgery.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A general meeting of this society will be held at 5.15 P.M. on Friday, June 11th, at 20, Hanover-square, W., at which the officers and council will be elected for the ensuing session, the annual report of the council will be received, and the proposed amalgamation of the society with the Royal Society of Medicine, recommended by the council, will be discussed. An address will be delivered subsequently by *Sir James Barr on the Peripheral Circulation and its Treatment.* At 7.30 o'clock on the same evening the annual dinner of the society will take place at the Georgian and Adams Rooms, Piccadilly Restaurant, when the President, Mr. Ernest Solly of Harrogate, will take the chair. The President has arranged for an entertainment, at which the Misses Ridley, classical dancers; Mr. Byrd Page, prestidigitateur; and Miss Edith Wesley, contralto, will appear. The price of the dinner ticket is 7*s.* 6*d.*, exclusive of wine.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. J. A. D. Shipley of Gateshead the following bequests amongst others are made:—£2000 to the Royal Infirmary for the Sick and Lame Poor of Newcastle-upon-Tyne, Northumberland, and Durham; £1000 to the University of Durham College of Science, Newcastle-upon-Tyne; £300 to the Fleming Memorial Hospital for Sick Children, Newcastle; £300 to the Hospital for Sick Children, Gateshead; £300 to the Northern Counties Blind Asylum, Newcastle; £250 to the Newcastle-upon-Tyne Dispensary; £250 to the Gateshead Dispensary; £250 to the Prudhoe Convalescent Home, Whitley; £200 to the Eye Infirmary, St. Mary's-place, Newcastle; £200 to the Northern Counties Institute for the Deaf and Dumb, Newcastle-upon-Tyne; £200 to the Throat and Ear Hospital, Saville-row, Newcastle; £200 to the Hospital for Diseases of the Throat and Ear, Clayton-street, Newcastle. The residue of the testator's estate will eventually be divided amongst these institutions, each of which will receive bequests equal to a [illegible] stated above.—By the will c [illegible] Clifton, Bristol, the Churcl [illegible] Auxiliary) will receive a speci [illegible] quently an additional sum of about £12,000.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—The annual meeting of this association was held on May 28th at 11, Chandos-street, London, W., Mr. H. Brunton Angus being in the chair. The treasurer's report was agreed to after some criticism. The following officers were then elected: Dr. W. Rawes, President; Dr. T. Beattie and Dr. M. G. Biggs, Vice-Presidents; Dr. W. Martin and Dr. J. Inglis Parsons, honorary secretaries; and 18 members of council and three auditors. Dr. Rawes, Dr. Martin, and Dr. T. M. Allison were elected representative governors of the court of the Durham College of Medicine. The report of the subcommittee on the University Bill was approved. Sir T. Lauder Brunton and Dr. F. W. Mott were unanimously elected honorary members of the association. The members and their guests dined together the same evening at the Café Royal, Dr. Rawes, the new President, being in the chair. The toast of the "University of Durham" was proposed by Mr. H. Brunton Angus and responded to by Sir George Hare Philipson; that of "The Association" was proposed by Dr. Mott and responded to by Dr. Parsons. The toast of "The Guests" was proposed by Dr. F. M. Sandwith and responded to by Sir James Barr in humorous terms. Among those present were Sir Henry Burdett, Dr. C. A. Mercier, the Master of the Society of Apothecaries, Sir W. H. Allchin, Mr. T. H. Openshaw, Dr. C. W. Chapman, Dr. F. S. Palmer, and others. Some excellent music was provided by Mr. A. E. Godfrey and a most enjoyable evening was passed.

WORTHING HOSPITAL.—In accordance with the decision of the committee of management of the Worthing Hospital on May 14th to increase the honorary medical staff, the committee on May 28th elected the following gentlemen: Mr. H. F. Hyde, Dr. H. Leeds Harrison, Mr. E. H. Good, and Mr. P. J. Le Riche.

THE WEST AFRICAN MEDICAL STAFF.—The summer dinner of the West African Medical Staff will take place on Monday, June 21st, at the New Gaiety Restaurant, London. Members of the staff who intend to be present should communicate without delay with Dr. W. T. Prout, C.M.G., 78, Rodney-street, Liverpool.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.—The annual general meeting of the members of this society was held in the rooms of the Medical Society of London on May 27th. The report for 1908 shows the society to be in a thoroughly sound condition. At the end of the year the total membership amounted to 2723, being an increase of 140 over that of the previous year. The funds amount to £223,994 after the disbursement of £14,447 in sickness benefit during the year. The present annual income from sick insurance premiums is £17,010. Since the society was founded in 1884 over £140,000 have been paid out in sickness benefit to members. As the recent quinquennial valuation shows a surplus of £9040 in the sickness fund, all members entitled to its benefits receive at the age of 65 a 10-guinea bonus for every guinea per week of sick benefits to which they have become entitled during their membership with a proportionate sum to those who have increased their sick benefit amounts. As a surplus of £4303 exists on the life assurance branch a bonus of 15 per cent. on the sum assured is to be added to all payments made in response to claims on life assurance contracts falling due during the present quinquennium. In pursuance of this policy of the society £13,000 have already been paid out as bonus money. The society is open to all male members of the medical profession or Licentiates in Dental Surgery practising in the United Kingdom. The chairman of the executive committee is Dr. F. de Havilland Hall and the secretary of the society is Mr. F. Adiscott, F.I.A., 33, Chancery-lane, W.C.

LIVINGSTONE COLLEGE.—Commemoration Day was celebrated at Livingstone College, Leyton, on May 26th, in the presence of a large gathering, under the presidency of the Very Rev. Dr. Butler, Master of Trinity College, Cambridge. The Principal, Dr. C. F. Harford, in his opening statement, commented on the great progress which had taken place since Professor A. Macalister gave the inaugural address in the first premises of Livingstone College 15 years ago. Public opinion had entirely changed as to the necessity of medical training for missionaries, and it was now regarded as an absolute necessity for missionaries to have some medical knowledge. The Master of Trinity referred to the loss of Bishop Mackenzie, of his own sister, wife of the late Bishop Brown, and of other missionaries from fever, and said that the training given at Livingstone College would save many such valuable lives. Professor Macalister said that though doubts had been expressed as to the wisdom of the training given, he thought that these doubts had long since been laid aside, and as an old medical teacher he had thorough confidence in the course of training given at the College. From his experience in many parts of the world, especially in Syria and in China, he believed that it was a necessity for a missionary to be able to render simple medical aid to the natives, and in the absence of qualified medical aid it was most important that ordinary missionaries should have such elementary medical training as is given at Livingstone College. He hoped that before long some such training would be regarded as an absolute necessity for every missionary. Dr. M. A. Stein, the intrepid Central Asian explorer, bore testimony to the skill and kindness of an old student of Livingstone College, who had rendered him valuable surgical aid for frost-bite when travelling in the Himalayas. Mr. W. McAdam Eccles moved a hearty vote of thanks to the chairman and speakers. The meeting terminated with the Benediction, which was pronounced by the Master of Trinity.

BRIGHTON SCHOOL CANTEENS.—Some interesting figures were given in the annual report of the Brighton elementary schools canteen committee submitted to the education authority at its meeting on May 25th. The report dealt with 12 months from May 5th, 1908, to May 3rd, 1909, covering, as it did, the second year's working of the free meal distribution in the borough. It appeared that of 17,257 children on the books 1427 (or 8 per cent.) received free meals. In the year previous the number of children receiving free meals was 1213. The total number of free meals granted was 113,490, or an increase of 27,288 upon the previous year. This great increase was not explained when the report was presented to the education committee, but evidently the authority is quite satisfied inasmuch as it passed the report without comment and resolved "that, feeling satisfied that there are children in the elementary schools who are unable, by reason of lack of food, to take full advantage of the education provided for them, also that funds other than public funds are not available, the Brighton town council be requested to make application to the Board of Education under Section 3 of the Education (Provision of Meals) Act, 1906, for sanction for the spending of £500 from the rates during the financial year ending March 31st, 1910, for the purpose of defraying the cost of food furnished in meals under the Act." The cost to the rates for the provision of food was £427 3*s.* 2*d.*, and as £10 2*s.* 8*d.* had been received by the sale of 1*d.* dinners and surplus food the net cost to the rates for food was £417 0*s.* 6*d.* The gross cost of the canteens was £737 15*s.* 1*d.* and the net cost £727 12*s.* 5*d.*

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Whitsuntide Holidays.

BOTH Houses of Parliament have had an adjournment for the Whitsuntide holidays. The House of Lords will not meet again until June 23rd, but the Commons were only able to take a week's vacation. Parliament is to all appearance entering on a very strenuous period of the session. The Finance Bill, which has now been published, is a very long and complicated measure, bristling with points of controversy. The Opposition regards many of its proposals with undisguised hostility, and a long and keen Parliamentary fight may be expected in consequence. Many Members of the House of Commons were disappointed that in anticipation of the physical strain which may be put upon them in the next three months in sitting late the holidays were not longer.

The Tuberculosis Order.

A motion has been passed by the House of Commons for the presentation and publication of the Tuberculosis Order of 1909 and of a Circular Letter issued by the Board of Agriculture and Fisheries to local authorities in Great Britain under the Diseases of Animals Acts, 1894 to 1903. The Order in question has an important bearing on the milk legislation of the Government.

Experiments on Living Animals.

A return has been ordered showing the number of experiments on living animals during the year 1903 under licences granted under the Act 39 and 40 Vic., c. 77, distinguishing the nature of the experiments.

The Superannuation of Asylum Officers.

A considerable amount of evidence has been taken by the Select Committee of the House of Commons on the subject of the superannuation of asylum officers. Amongst the witnesses on May 25th was Dr. BOWER, Bedford, chairman of the Parliamentary Committee of the Medico-Psychological Association. He stated to the committee that in the absence of a guaranteed pension system the asylum service had not always the same inducements as other branches of the public service to offer in order to attract the best possible recruits The Association cordially welcomed the principle of the Bill.

HOUSE OF COMMONS.

WEDNESDAY, MAY 26TH.

Malaria in the Colonies.

Mr. RAMSAY MACDONALD asked the Under Secretary of State for the Colonies whether the 11 colonies which made no special report on malaria, in response to the circular of June 6th, 1906, had since been communicated with and had been asked to furnish reports.—Colonel SEELY replied: Yes, sir. A special circular has recently been sent out by the Secretary of State with a view to obtaining fuller information with regard to anti malarial measures, both from the colonies to which my honourable friend refers and from other tropical colonies.

Mr. RAMSAY MACDONALD further asked whether the Colonial Office had made any representation to the Government of St. Kitts-Nevis [illegible] elective body.

The Prevention of Disease in Gaelic-speaking Districts.

Mr. WEIR asked the Lord Advocate whether, in view of the statement contained on page 32 of the recently issued report of the medical officer for Ross and Cromarty, he would state whether the leaflets [illegible] translated into Gaelic and [illegible] Lewis, as soon as possible. [illegible]

The Infectious Diseases Hospital, Stornoway.

[illegible] friend.

Mr. WEIR: In view of the urgency of the matter will the right honourable gentleman ask the Secretary for Scotland to approach the Chancellor of the Exchequer with a view to getting the necessary money out of the millions which he is raising?—Mr. URE: I shall make the effort, but I cannot hold out hope that it will be successful.

The President of Madras Medical College.

Mr. MOONEY (for Mr. KETTLE) asked the Under-Secretary of State for India whether the present president of the Medical College, Madras, was appointed to that post after having acted as surgeon on the personal staff of three successive governors of Madras, and what [illegible]

Enteric Fever amongst Soldiers.

Captain CLIVE asked the Secretary of State for War whether he was [illegible] question evidently refers to the seven non-commissioned officers and men under treatment at the Millbank Military Hospital. I am informed that [illegible] their comrades [illegible] mendation of [illegible] special treatment to see if their condition is curable. This treatment has met with encouraging results and one at least of the cases, it is hoped, has been cured. Although patients in hospital, they are allowed considerable freedom and are not treated as ordinary patients. [illegible] say how long [illegible] of the bacilli [illegible] not quite unproved?

Mr. HALDANE: No, I do not think so. The advance in medical science on this subject within the last two years has been enormous.

Mr. JOHN WARD: Are these experiments being made with the sanction of the men; and in case of permanent injury to their health will the men be pensioned?

Mr. HALDANE: I do not know why the honourable member treats these as experiments. They are a well-known ascertained cure.

The Medical Examination of Yeomanry Recruits.

Mr. MARTEY THOMPSON asked the Secretary of State for War whether he was aware that it was frequently the case that medical men were allowed only 1s. per head for every Yeomanry recruit who was passed, and that they received no payment for the examination of recruits who were not passed, and whether he would consider the advisability of amending this system, which offered a distinct inducement to medical men to pass recruits who on the outbreak of war [illegible] Mr. HALDANE replied: The fees paid [illegible] at the discretion of the county [illegible] to the 1s. rate when payment is [illegible] paying for men examined but not passed.

Poor-law Statistics in Ireland.

Dr. AMBROSE asked the Chief Secretary to the Lord Lieutenant of Ireland what was the number of persons in receipt of indoor relief in Ireland during the year ending March 31st, 1909, exclusive of children and the sick; what was the number of children in the workhouses during the same period; what was the number of sick in union hospitals in the same period; what was the number of persons on outdoor [illegible]

Appointments.

[illegible] Vacancies, Secretaries of Public Institutions, [illegible] information suitable for this column, are [illegible] THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BAGNALL, R. G. A., M.B., Ch.B. Edin., has been appointed Assistant Medical Officer at the Newcastle-on-Tyne City Asylum, Gosforth.

BALY, A. L., M.R.C.S., L.R.C.P. Lond., has been appointed First Assistant Medical Officer at the Lambeth Infirmary.

BIDIE, EVAN, L.R.C.P. & S.Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer at Wye House Asylum, Buxton.

BYGOTT, ALBERT HENRY, M.D. Lond., D.P.H. Birm., Barrister-at-law, has been appointed Medical Officer of Health of Barking.

HAILES, C. D. G., M.D. Edin., F.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bristol District of the county of Gloucester.

HALL, JOHN BASIL, M.B., B.C. Cantab., F.R.C.S. Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 11, to be attached more particularly to Bradford, Keighley, Otley, and Skipton County Courts.

RISELEY, STANLEY, M.D. Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuits Nos. 13 and 18.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHLEM HOSPITAL.—Two Resident House Physicians, unmarried, for six months. Salary at rate of £25 each per quarter, with apartments, board, and washing.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £170 per annum, with rooms, fire, lights, and attendance.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Resident Medical Officer. Salary £150, with board and residence. Also House Surgeon for six months. Salary at rate of £75 per annum, with board and residence.

BOURNEMOUTH, ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.—House Surgeon, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—House Surgeon, unmarried. Salary £130 per annum, with board and residence.

BRITISH EAST AFRICA, CHURCH OF SCOTLAND MISSION, Kikuyu.—Medical Missionary.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon also Assistant House Surgeon, both unmarried. Salaries £80 and £60 per annum respectively, with board, lodging, and washing.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.

CENTRAL LONDON SICK ASYLUM, Colindale Avenue, The Hyde, Hendon, N.W.—Assistant Medical Officer and Dispenser. Salary £110 per annum, with board and residence.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with board, apartments, and laundry.

CHINA, CHURCH OF SCOTLAND MISSION, Ichang.—Medical Missionary.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with residence, board, and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—[illegible] Salary at rate of £60 per annum, [illegible]

EXE[illegible] HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

HAMPSHIRE COUNTY COUNCIL.—Assistant County Medical Officer of Health. Salary £250 per annum, and allowances.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board and residence.

INDIAN MEDICAL SERVICE, India Office, London.—Twenty-one Commissions.

INVERNESS, NORTHERN INFIRMARY.—House Surgeon. Salary £100 per annum, with board, &c.

IPSWICH, EAST SUFFOLK HOSPITAL.—Senior House Surgeon. Salary £80 per annum.

KINCARDINE (ROSS-SHIRE) PARISH COUNCIL.—Resident Medical Officer and Vaccinato[illegible]

KING'S COLLEGE [illegible]

KING'S COLLEGE [illegible] Psychological Medicine.

LEEDS GENERAL INFIRMARY.—Resident Surgical Officer; also Resident Casualty Officer. Salaries £150 and £125 per annum respectively, with board, lodging, and washing. Also Honorary Assistant Surgeon.

LINDSEY (LINCOLNSHIRE) EDUCATION COMMITTEE.—Two School Medical Inspectors. Salary £300 per annum.

LONDON HOSPITAL MEDICAL COLLEGE.—Assistant to the Bacteriologist and Lecturer on Bacteriology.

LONDON MEDICAL MISSION, Endell-street, W.C.—Medical Officer, unmarried. Salary £100 per annum, with board and lodging

LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon, for six months. Salary at rate of £75 per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead.—Junior Resident Medical Officer. Salary £[illegible] per annum, with board and residence.

NORWICH, JENNY LIND INFIRMARY FOR CHILDREN, Unthank-road.—Resident Medical Officer (female). Salary £50 per annum, with board, apartments, and laundry.

NORFOLK COUNTY ASYLUM, Thorpe, Norwich.—Second Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, attendance, and laundry.

QUEENSLAND, AUSTRALIAN INSTITUTE OF TROPICAL MEDICINE, Townsville.—Director of the Institute.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Lecturer on Physiology.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Resident Surgical Officer, House Physician, and Junior House Surgeon. Salaries £120, £100, and £50 per annum respectively, with apartments, board, and washing.

WALSALL AND DISTRICT HOSPITAL.—House Surgeon, also Junior House Surgeon. Salary of former £100 and of latter £80 per annum, with board, residence, &c.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician, unmarried. Salary £65 per annum, with board, residence, &c.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £80 per annum, with apartments, board, and laundry.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Two House Surgeons. Salary £80 per annum, with board, lodging, and laundry.

WORCESTER GENERAL INFIRMARY.—House Physician. Salary £100 per annum, with board, residence, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Lostwithiel, in the county of Cornwall; and at *Cleland*, in the county of Lanark.

Births, Marriages, and Deaths.

BIRTHS.

ALMOND.—On May 31st, at Lynvale, Bath, the wife of G. Hely-Hutchinson Almond, M.A., B.M., Ch.B. Oxon., M.R.C.S., L.R.C.P., of a son.

BALFOUR.—On May 29th, at Court Lodge, Deal, the wife of Andrew Balfour, M.D., of Khartoum, of a son.

EAST.—On May 28th, at 2, North-road, Clapham Park, S.W., the wife of William Norwood East, M.D. Lond., of a daughter.

STEWART.—On May 29th, at Dyffryn, Dulwich, the wife of H. M. Stewart, M.A., M.D., of a daughter.

TURNER.—On May 30th, at Westbury, Purley, Surrey, the wife of Sydney Duke Turner, M.D., B.S., D.P.H., of a son.

MARRIAGES.

GOOD—ANGUS.—On June 1st, at St. Mungo's Church, Balerno, Midlothian, Edgar Hubert Good, M.R.C.S., L.R.C.P., eldest son of the late Edward John Gregory Good, of Long Ditton, Surrey, to Alice Josephine, daughter of the late Joseph Angus, of Hampstead.

LYLE—PLAYFAIR.—On May 27th, at Christ Church, Mayfair, Herbert Willoughby Lyle, M.D., F.R.C.S., to Annie Seaton, widow of David Thomson Playfair, M.D., F.L.S., and daughter of Edwin William Winton of Speldhurst, Kent.

DEATHS.

CRIPPS.—On May 25th, at Thomas street House, Cirencester, Edward Charles Cripps, M.R.C.S., L.R.C.P., aged 54 years.

HAMES.—On May 28th, George Henry Hames, F.R.C.S.

RAMSDEN.—On June 1st, after a long illness, Henry Kay Ramsden, M.B., B.Ch., aged 42 years, of 102, Sloane-street, Chelsea. Funeral at Saddleworth, Yorkshire, on June 6th.

SHEPHERD.—On May 28th, at Finchley, J. Brooks Shepherd, M.R.C.S., formerly of 8A, New Cavendish-street, in his 75th year.

SYMINGTON.—At 17, Strathearn-place, Edinburgh (the residence of Hippolyte Blanc, R.S.A.), on May 29th, Juliet, wife of Dr Symington, Professor of Anatomy, Queen's College, Belfast, and daughter of the late William Bryce, architect.

N.B.—A fee of [illegible] of Births, [illegible]

Notes, Short Comments, and Answers to Correspondents.

MENTAL DISEASES IN THE ORIENT.

Dr. Massar Bey, professor of neurology in Stamboul, has published recently an instructive study of mental disease. In an especially interesting chapter he deals with the differences in origin of insanity as manifested in the Orient and Western Europe respectively. It is generally accepted that mental diseases are of rarer occurrence in the East than in the West. Dr. Massar Bey gives the following reasons. Of the numerous poisons that undermine the bodily health and ruin *the nervous system of Europeans many are quite unknown in the* East, or known only in a very slight degree. This is the case for instance, with lead poisoning resulting from industrial occupation, while morphine, cocaine, and atropine are hardly ever used by the Eastern. Oddly enough, it is very seldom that victims of the opium or hashish habits are found in asylums. Foremost consideration of all is the fact that the pernicious effects of alcoholism, which account for so many nervous and mental diseases in the West, are absolutely unknown in the East. The Oriental uses alcohol only in exceedingly rare cases. It is the religious duty of the follower of Islam never to touch alcoholic drinks, but the non-Mussulman population also are much more sober in Eastern countries than in Europe. Thus Jews and Armenians are hardly ever seen drunk. Ailments, therefore resulting from the excessive use of alcoholic drinks are very seldom met with. Other causes of the rare occurrence of mental disability in the East are to be found in the modes and habits of living and in the ethical precepts of its peoples. The fatalistic trend of mind of an Oriental saves him from excessive worry and grief over the death of a beloved person or the loss of a valuable property. His religion helps him in a remarkable way. The acceptance of kismet is the guiding rule at every turn of life. Dr. Massar Bey says that Mahomedan *children are taught in their early school days to learn entire sub*missiveness to the unavoidable decrees of kismet, and summarises this philosophy in somewhat remarkable words: "We aspire in our spiritual activity to an abiding and logical ideal. All our existence is due to but a mere chance. What we possess does not cause us the highest satisfaction and joy, because we think that it is not ours. Its loss therefore never puts us into a state of inconsolable mourning. We work in the hope of success, but if success does not follow we quietly consider that it is not our fault, that all lies in the hands of kismet." Another advantage on the side of many an Oriental is to be found in the simplicity and natural manner of his living. He has no exciting evening entertainments, no balls, no late hours of amusement. He despises excess of every sort and he looks for his happiness to his family life.

AN INVESTIGATION INTO THE INDUSTRIAL EMPLOYMENT OF MARRIED WOMEN.

To the Editor of THE LANCET.

SIR,—The investigation committee of the Women's Industrial Council is making an extensive inquiry into the industrial employment of married women—a subject upon which there is a great lack of detailed and classified information. As a rule, the inquiries of the council are confined *to London, but it has been felt* necessary to carry this one into other parts of the country, and the expenses will be correspondingly increased. Voluntary assistance has been and is being, given, and 300 to 400 cases have already been collected and in part tabulated, but much remains to be done, and the funds of the council, never large, must be supplemented by further contributions from the general public. It is estimated that at least £500 will be [illegible] any adequate manner [illegible] a large body of facts concerning the [illegible] be of especial value to the various [illegible] it will probably throw light upon infant mortality and physical deterioration as well as upon many industrial and some social problems. Its value in all these directions, [illegible] tradict, and we boldly ask for money to help in carrying out this useful work. Contributions should be sent to Miss L. Wyatt Papworth, secretary, Women's Industrial Council, at the office, 7, John-street, Adelphi, Strand.—We [illegible]

May 21st, 1909. L. WYATT PAPWORTH, Secretary.

LYNN THOMAS AND SKYRME FUND.

THE following additional subscriptions to the above fund have been received: *J. D. Williams (Cardiff)* £1 1s., *S. J. O. Fraser (Hastings)*, and W. C. Griffiths (Pontardulais), £2 2s.

THE RELATIVE IMPORTANCE OF SODIUM AND CALCIUM IN THE CAUSATION OF GOUT AND GOUTY DEPOSITS.

IN the *Bio-Chemical Journal* for February, Dr. W. G. Little recorded some interesting experiments which he has made on the solubility of the various salts of uric acid at the temperature of the body in water and in saline solution. In distilled water potassium biurate is soluble 1 in 550, sodium biurate 1 in 1030, magnesium biurate 1 in 2440, and calcium biurate 1 in 4760. When the distilled water was replaced by ½ per cent. solution of sodium chloride it was found that while the solubilities of the biurates of calcium and magnesium were somewhat increased, that of sodium biurate was reduced almost to zero. This result, it is thought, probably gives the key to two phenomena: first, the preponderance of sodium biurate in the body in gouty concretions, and secondly, the value of certain saline mineral waters empirically used in gout, their value depending upon the increased solubility of the biurates of calcium and magnesium in saline solutions. Attention *is specially directed to the relatively small amount of sodium chloride* [illegible] may have profound effects on the solubilities of the biurates in the body. In the language of physical chemistry, the effect of sodium chloride upon the solubility of sodium biurate may probably be referred to the mass action of the common sodium ion tending to throw out of solution the less soluble salt—viz., sodium biurate. Dr. Little has also found that the addition of even small percentages of calcium salts to distilled water had the effect of very much lessening its solvent power on sodium biurate. The experiments tend to show that the formation of deposits and tophi may be largely influenced by the presence of calcium salts. Dr. Little records two cases met with in his practice which afford suggestive evidence that sodium chloride is connected with gouty joint phenomena. In one of the cases a child aged five years developed acute arthritic symptoms in the feet and thighs, simulating acute rheumatism, after an overdose of sodium chloride given in the form of an enema for intestinal worms. The pathogenic significance of the sodium chloride was proved by the fact that as soon as its administration ceased, with no other medication except small doses of potassium citrate, the child rapidly became *and remained well. In the other case the enjoyment of a course of* boiled ham was followed by podalgic gout, first in one great toe joint and then in the other. Analyses of the urine collected when the attack was at its height and again when recovery was well advanced [illegible]

AN ETHNOLOGICAL THEORY OF PARASITIC DISEASE.

To the Editor of THE LANCET.

SIR,—The April number of *Janus* contains an article to which I should like to call the attention of physicians and historians. The writer, Dr. Otto Effertz, a governmental vaccinator in Mexico, attempts *to prove that the virulence of an infectious disease is not absolute but* relative, being the resultant of two factors varying according to the country in which the disease is endemic and the people who are attacked by it. These factors are: (1) the virulence of the microbe, which differs in different co[illegible] immune thro[illegible] the result of [illegible] natural selection evolves more powerful micro-organisms. On the other hand, a race of men is evolved more capable of resisting them. The resultant represents the malignity of the disease, and it will vary as the factors vary. Dr. Effertz then notices two remarkable facts: (1) African malaria is deadly for Europeans, but very mild for Africans; (2) American malaria is deadly for American Indians, but mild for Europeans. He infers (*a*) that the African parasite has grown more virulent during the thousands of years it has been in Africa; (*b*) *that the American parasite is much less virulent, having been* recently carried to America. The African negro has won his battle, the European has partly won it, the American Indian has yet to win it. The European is superior to the American parasite but inferior to the African parasite. The Indian is inferior, the African negro superior to both.

Dr. Effertz applies similar reasoning to syphilis and yellow fever. He holds that the Spaniards could not have carried out their conquests if the continent had been as fever-stricken as it is now, and as a matter of fact history tells us little about fever in those days. Malaria was probably brought over from Europe; it now kills over 50 per cent. of all Mexican Indians. America is credited, by way of return, with having given syphilis to Europe.—I am, Sir, yours faithfully,

W. H. S. JONES.

St. Catharine's College, Cambridge.

CHILDREN'S COUNTRY HOLIDAYS FUND.

WITH its recent annual meeting at the Hotel Metropole the Children's Country Holidays Fund completed the first 25 years of its existence. That the number of children sent away year by year has increased [illegible] sufficient proof that the work has [illegible] and the total sent during the [illegible] voluntary subscriptions totalled [illegible] or further funds to continue and extend the work Canon S. A. Barnett, the chairman of the Fund, points out that there are 800,000 children in the elementary schools of London, for whose benefit the Fund exists.

That the parents appreciate the efforts made on their behalf is evidenced by the fact that they contributed in small sums no less than £9875 towards the cost, an average of about 4*s.* 2*d.* per child, the total expenditure being about £31,000. It would not be possible to send away this number of children were it not for the untiring efforts of the voluntary workers in town and country, who number over 2000. Although the number sent is large, the present yearly total is not 6 per cent. of the elementary school population. Far more ask to go away, but they cannot be sent without a largely increased subscription list and further personal service. We have pleasure in seconding the council's earnest appeal for further help, as the fund is undoubtedly working in the real interest of the public health. Contributions should be sent to the treasurer, the Earl of Arran, 18, Buckingham-street, Strand, London, W.C.

◆

Oyster.—Our correspondent evidently has in mind an article which appeared in THE LANCET of Jan. 3rd, 1903, p. 71, in which we gave an analysis of the oyster and an account of its solubility in various beverages, of which diluted gin appeared to be the most effective, then chablis, whilst in stout the mollusc was practically insoluble.

Sero sed serio.—The story as told is not quite comprehensible. We must be trusted with a full account before we give any definite reply, but there does not seem to be reason for a cessation of the usual professional relations.

Lex.—We consider that the General Medical Council would take action on the information submitted by our correspondent.

ERRATUM.—Mr. H. W. Bayly, in his paper on "The Serum Diagnosis of Syphilis" published in THE LANCET of May 29th (p. 1523), acknowledged his thanks to Mr. W. J. C. Keats for allowing him access to cases. In this acknowledgment Mr. Keats was described inadvertently as medical superintendent of the Hammersmith Infirmary instead of the St. Giles's Infirmary, Camberwell.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Herbert F. Waterhouse, Walter G. Spencer): at 5.30 P.M.

Papers:

Mr. Walter G. Spencer: Benign Tumours—Fibroma, Myoma, Lipoma—Encapsuled in the Wall of the Stomach.

Mr. E. Stanmore Bishop: Some Cases of Gastric Surgery.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—H. Beckett-Overy, William J. Gow): at 7.45 P.M.

Specimens:

Dr. G. E. Purslow: (1) Uterus, with Fibroid Tumour, from a Case in which Cæsarian Hysterectomy was performed; (2) Bilateral Ovarian Tumours, One of which Obstructed Labour on Two occasions.

Dr. W. J. Gow: Cancer Originating Separately in the Uterine Body and in the Cervix.

Short Communications:

Mr. J. Bland-Sutton [illegible] Fibroid, associated with [illegible]

Dr. G. Darwall Smi[illegible] Ovary.

Dr. Kedernath Das: Fœtal Chondro dystrophia.

Papers:

Dr. J. S. Fairbairn: Primary Chorion Epithelioma of the Ovary.

Dr. Blair Bell: A Case of Rudimentary Uterus Didelphys, with Ectopia of Each Uterine Body in an Inguinal Hernia Sac; with Some Remarks on the Development of the Female Genital Organs.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—8.30 P.M., Captain E. B. Waggett, R.A.M.C. (T.): The Mouth, Nose, Throat, and Ear from the Point of View of Recruiting.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Specimens will be shown by Mr. F. Fergus, Mr. F. W. Edridge-Green, Mr. A. Lawson, Mr. J. H. Fisher, and others. 8.30 P.M., Mr. W. H. H. Jessop: The Report of the [illegible] the Unification of the Notation of Meridians of Astigmatism.—Mr. [illegible] with Congenital Displacement of [illegible] Congenital Opacities of Lenses.—Mr. A. [illegible] and Mr. A. W. Ormond: A Case of Retinal [illegible] Dr. G. M[illegible]

FRI[illegible] Mr. Nettleship: Some Diseases [illegible] (Bowman Lecture).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, [illegible] Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M. Lecture:—Dr. W. H. B. Stoddart: The Early Signs of Ment Disorder.

TUESDAY.—4 P.M., Dr. L. Guthrie: Clinique (Medical). 5.15 P.M. Lecture:—Dr. H. Mackenzie: Diagnostic Methods in Tube culosis.

WEDNESDAY.—4 P.M., Mr. E. L. Evans: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. F. Jaffray: Appendicitis—Symptoms a Diagnosis.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgica 5.15 P.M., Lecture:—Mr. J. Clarke: The Clinical Examinati of Spinal Cases.

FRIDAY.—4 P.M., Dr. D. Grant: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmit road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration Cases in Wards. 12 noon, Pathological Demonstration—D. Bornstein. 2 P.M., Medical [illegible] Mr. Dunn: Diseases of the Eye [illegible]

TUESDAY.—10 A.M., Dr. Moulli[illegible] 12.15 P.M., Lecture:—Dr. [illegible] 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr Etherington-Smith: Clinical.

WEDNESDAY.—10 A.M., Dr. Davis: Diseases of the Throat, Nose and Ear. Dr. Saunders: Diseases of Children. 12.15 P.M. Lecture:—D[illegible] and Surgica[illegible] 2.30 P.M., [illegible] 5 P.M., Lect[illegible]

THURSDAY.—10 [illegible] of Cases in Wards. [illegible] X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Keetley: Clinical (with cases).

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

An Address

ON

THE MODERN TREATMENT OF FRACTURES.

Delivered at the Annual Meeting of the Cardiff Medical Society on June 4th, 1909,

By JUST LUCAS-CHAMPIONNIÈRE,

HONORARY SURGEON TO THE HÔTEL-DIEU, PARIS; MEMBER OF THE FRENCH ACADÉMIE DE MÉDECINE; PRESIDENT OF THE INTERNATIONAL SOCIETY OF SURGERY.

GENTLEMEN,—I no doubt owe the honour you have done me in asking me to deliver an address on this occasion to the fact that I am an old student of the British universities. When I was a young man, soon after completing my studies in Paris I paid a visit to this island, early enough to see the surgical science of Lister at its dawn, and I am happy to-day to remember and to state that since that time I have been among those who have always rendered just homage to the science of your country. This is not because, like certain philosophers, I think that Science has no country; on the contrary, I believe that we ought to be as proud of our country's men of science as of our great soldiers. But the man of science is fortunate in that he is imbued with an additional sentiment added to the love of his own country, and that is a sincere admiration and brotherly sympathy for all those who in foreign countries have enriched the science to which he himself has devoted his life.

The best way of proving sympathy and sincere admiration for a scientific association which meets to celebrate a long and laborious past is to present to it a review of a subject to which the speaker has for many years himself given much attention. I propose, therefore, on this occasion to speak on the modern treatment of fractures, not only because I believe firmly in the efficacy of a mode of treatment which I myself introduced, *but also because the profession in this country is* still under the influence of the righteous emotion caused in the surgical world by the unjust accusation to which your compatriots were subjected. That it is possible for such injustices to occur is due not merely to the existence of a feeling unfriendly to the medical profession, but also to the important changes which the method of treating fractures has recently undergone, changes not fully known to the medical world, and still more imperfectly known to the non-medical public. The importance and gravity of the subject will, I hope, interest you sufficiently to induce you to forgive any deficiencies in my address.

TREATMENT BY REDUCTION AND SPLINTS.

The truth is that within recent times the classical treatment of fractures has been undergoing a radical change. It is a remarkable fact that the treatment of fractures, the beginnings of which go back so far into the mists of time that we have no idea of the era when splints and treatment by immobilisation were invented, has always rested upon the same data and upon the same principles ever since the first beginnings of the science of surgery. Read any treatise on fractures, from the most ancient to the most modern, from Hippocrates to Ambroise Paré, to Dupuytren and Malgaigne and Hamilton; read all the encyclopædias, even the titles of which I cannot enumerate—every one of them will tell you that movement is the enemy of the formation of callus and of bony repair; that it is an obstacle to the formation of callus, so that defective consolidation, whenever it is observed, is attributed to movement having been permitted. In order to obtain the union of fractures all practitioners have taken account of one fact alone—that a bone is a rigid lever. When it is broken the fragments must be fixed in the position of the normal bone and immobilised. To reduce and to immobilise are the only measures upon which attention is riveted.

Ambroise Paré, the first surgeon who boldly relied on his own personal observation, whose imagination was always alive to find out something new, often hesitates between his own imagination and the ancient traditions as to fractures, but he ends up always with remarks which impel him to greater exactness and greater violence to ensure the reduction of fractures and their maintenance in position. Beyond this he gives information only as to the drugs which might favour the production and the union of bone. With the exception of this last point, the aims of Dupuytren, of Malgaigne, and of Hamilton are exactly the same, although, like all nineteenth century writers, being convinced that they possess much more accurate views on anatomy and physics than the older writers, they apply procedures for reduction and maintenance still more rigorously, and invent new details in the methods of reduction and in splints. The strange thing is that they are so persuaded that they really reduce fractures, and that they favour union by immobilisation, that they pay little or no heed to clinical observation. It does not occur to them to try any other means. If their results are bad, their only thought is to attribute the failure to the inadequacy of the means of reduction and immobilisation which they had adopted. Here and there in their writings on fractures it can be clearly perceived that some great observers were disturbed by facts which, as it were, struck them in spite of themselves. Malgaigne had, indeed, seen untoward results due to muscular contraction in fractures of the lower limb, and he thought that in the inclined plane he had found a means of preventing them. Hamilton, speaking of fractures of the elbow, recommends that the fragments should be immediately mobilised at the risk of not obtaining good adjustment, because it is essential to prevent ankylosis. Velpeau recommended that in fracture of the radius the splints should never be tightly applied, for fear of causing permanent ankylosis. The doubts expressed by these surgeons show that the evil consequences of immobilisation could not have been altogether unknown to them, yet not one of them was bold enough to run counter to accepted opinions; all soon returned to the employment of the most complete possible immobilisation after the most violent reduction. We find the greatest surgeons devising most extravagant appliances, such as Dupuytren's splints for fracture of the radius, the action of which is utterly futile, because, from a *point d'appui* in itself detestable, it has to oppose the contraction of the muscles and the cicatricial contraction at the site of the fracture; or again, that apparatus of Desault for fracture of the clavicle, which recalls the "Maiden," the torture jacket of the Middle Ages, under which the contraction of the muscles renders certain in the future the maximum possible deformity owing to overriding of the fragments of the bone.

Every one of these authors, not excluding even those who hesitated, all come back to the formula which Malgaigne very frankly placed at the head of his great treatise on fractures: "The treatment of fractures can be summed up in two great indications: Reduce the fracture and keep it reduced until consolidation is complete." The nineteenth century saw the birth of a considerable number of works on fractures; all of them rely, above everything else, on physical or geometrical theories of the mechanism of fractures; if they discuss treatment at all, it is only to describe new means for the forcible reduction of fractures and their maintenance in position.

TREATMENT BY IRREMOVEABLE APPLIANCES.

An enormous part in treatment of this kind has been played by a new invention—that of irremoveable apparatus. This method of treatment is extremely valuable in certain cases, but the infatuation for these appliances has been such that in a very large number of cases they are the cause of the very worst evils that can be produced by immobilisation. To realise the regrettable results of this absolute immobilisation upon the nutrition of the limbs we must come down to our own times. The problem presented by the treatment of fractures, which used to be "reduce, and maintain relative immobility," has now become "reduce, and enforce absolute immobility of one or several segments of the limb without regard to the duration of the immobilisation."

THE ORIGIN OF MODERN TREATMENT.

It was perhap [illegible] e evil produced by the abuse of [illegible] contributed to bring about an [illegible] ty for a change in treatment. S [illegible] ned, it was the excess of the evil which, more than any other fact, particularly struck me. The excess of the evil opened my eyes to the inconveniences of immobility, and to the part which mobility ought to play in the repair of fractures. This observation it was which emboldened me to make mobilisation a leading principle in the treatment of fractures. The success of the treatment has been due to the very numerous clinical observations which have demonstrated the truth of the principle. But to bring about an abrupt change in treatment, and to replace a bad by a good line of treatment, it is not alone sufficient for observers to recognise the existence of the evil. Our art must advance by slow steps, and it is well to learn how a change which upsets all the oldest principles could be made, how it could even enter the mind of an observer, and how it could be adopted by the majority of surgeons accustomed to another practice, which, although it presents many disadvantages, yet has for centuries rendered services at once incontestable and uncontested. This progress in therapeutics must be brought into relation with the great scientific changes by which modern surgery has been created. The paradoxical idea of introducing movement as a part of the treatment of fractures, and its acceptance by the medical public, must in fact have owed its development and its success to some very strong reasons.

Before making known the results of my own observations and experience I long meditated upon the facts and I can assert that I only made up my mind to publish conclusions contrary to all received ideas and to initiate a revolution in treatment, because I was witnessing and taking a part in the transformation which surgery was undergoing. Pasteur and Lister had so completely upset all our earlier notions that their example forbade any hesitation in submitting the best established scientific and practical theories to severe criticism. They inspired me with the courage which alone could lead to useful discoveries and transform what it is most difficult to transform—practices resting upon most ancient customs, such as are to be described by the word "routine." My assertions as to the remote consequences of the discoveries of Lister may be considered exaggerated, yet I am profoundly convinced of this indirect influence of a great piece of scientific work, and more especially of a piece of work which brought about a radical transformation not only in scientific theory but also in the mechanical execution of the details of the surgeon's own acts, a change which completely upset his habits in practice. This extraordinary piece of work which upset all our habits and destroyed the whole edifice of our surgical education, produced in us such an aptitude for change that I also found it possible to accomplish another piece of destructive scientific work, which, while it has its own dangers, can alone lead to great transformations in science and in practice. The relation of the change which I have advocated to our older education is in fact very singular. A distinguished American surgeon, Caldwell, of Freeport, who had assiduously followed my practice at the Beaujon Hospital and had watched my treatment in the various types of fractures treated there, said in summing the matter up: "It is a very strange thing, after spending all one's life as a surgeon and following scrupulously the precepts of surgery, to realise that one has been steadily deceived, and that in a practical matter so well established as the treatment of fractures one has been doing evil where one believed that one was doing good."

Is not this the very same idea that Sir William Bennett has sought to express in the introduction to his "Lectures on the Use of Massage and Early Passive Movements in Recent Fractures"?

> Indeed, it cannot but excite surprise in the mind of an intelligent person that the stiffness, pain, and other disadvantages which so constantly follow the treatment of fractures upon classical lines, should have been countenanced for so many years when they can, in the majority of cases, be entirely obviated by a treatment so simple as that described in the following lectures.

To break so completely with acquired habits, even when the change is the consequence of numerous positive observations, is in truth a revolution, and revolutions are only made when the reasons in their favour are many and strong. The transformation wrought in our scientific mentality, giving it a degree of boldness which might seem to be temerity, undoubtedly had a leading part in influencing my course. But the advance of surgery is always complex, and it must not be forgotten that other considerations influenced my mind, leading me to study the fundamental influence of movement on the vitality and on the regeneration of organs damaged or destroyed by injury. It is no doubt true that these considerations also have no very direct bearing, but they are the consequence of the advance of science and of the contemporary progress of medicine and physiology. When the study of many of the empirical methods of massage and gymnastics was commenced in France the study of movement was at the same time founded and developed. In this study two great French men of science were the chief leaders. Marey, by his methodical and in a certain sense mathematical study of all movements, taught us to register and reproduce them in pictures which were at once true and expressive; while Lagrange introduced medical analysis into the study of functional and gymnastic movements by applying the physical ideas of Marey to sport and training. It is, at any rate, the fact that my acquaintance with these two men of science contributed to lead me to study movement from the point of view of its physiological and pathological consequences in fractures and in injuries of the joints. Since that time a considerable number of men of science, teachers of gymnastics, masseurs, and others have carefully studied all the scientific facts bearing on the subject, and the present position of what is called physio-therapy is the result of a series of quite modern investigations.

The study of movement from the educational and therapeutic points of view seems to have originated in France during the last century. The aims of the gymnastic methods of Amoros and Laisné were at first educational, but their application in our country long remained very restricted, whereas in England and in America the love of sport gave origin to important empirical ideas with regard to movement and to training. It was, however, in Sweden and Norway especially that the study of movement from the educational point of view and the development of the art of massage were given a truly scientific character, and was controlled by men of science and doctors, while in every other country it remained the property of empirics. We must, in fact, not fail to recognise that the share of Sweden and Norway in the evolution of massage and gymnastics has been scientific. It must not be supposed that the fundamental difference between the system of gymnastics known as Swedish and other systems lies in any actual difference in the movements. The merit of the Swedish system of gymnastics lies in the application of scientific rules and of a definite method. The cause of its success is to be found in this methodisation. Various very different forms of movement are capable of giving equally successful results if they are measured and if they are performed on a regulated system. Again, it is the method or system which has rendered it possible to use this therapeutic procedure in many very different forms of education and treatment.

TREATMENT BY MASSAGE AND EARLY MOVEMENT.

With regard to the treatment of fractures which I advocate, I will say this, that my success has been due, more than anything else, to the introduction of a strict method of applying special forms of movement to the treatment of fractures. It is the method which has rendered possible the generalisation of this therapeutic measure and its application to all forms of injury of the skeleton and of the articulations. It is not unprofitable thus to recall the spirit of the method which served as a clue to guide me in working out a therapeutic revolution, and it is, in fact, true that each successive step can be traced in the history of my various trials and investigations, and in the order in which my various applications of the method succeeded one another. I began by lessening the degree of immobility; next I did away with it altogether; next I began to use movements at an early stage; then I began to use them immediately after the injury; finally, I made use of massage—that is to say, of a method of mobilising the muscles, the joints, and even the bony fragments. It was necessary to define the indications and the limits of this special form of movement. Thus it was that years of observation and experiment led me to establish the bold practice of methodical therapeutic mobilisation.

It is a singular thing to realise that it was through my own detailed studies that I did this, and that apart from my personal researches nothing was published before the appearance of the description of my method. The only instance in which massage had been used for a fracture at about the time at which I developed a complete method was for fracture of the patella; it was so used by Metzger, who apologised for applying massage to a fracture, on the ground, as he said, that in this particular fracture bony union could not be obtained. The same masseur, in discussing sprains of the ankle, stated specifically that massage should not be used if the malleolus was fractured. At the very same period I showed, in opposition to this, that massage favoured the production of new bone, and later the beautiful experiments of Cornil on animals proved that this result of the mobilisation of the fragments was invariably to be observed, and in young animals was too great. Having carefully studied all earlier observations which might have served as precedents for my method of mobilisation and massage, I have satisfied myself that none such existed.

SUTURE OF BONES.

Since my method was devised and generalised two important means for the study and the treatment of fractures have seen the light of day; these are suture of bones and radiography. I do not wish to decry immediate suture of *fractured bones. When Sir Hector Cameron performed the* first suture of the patella, when Lord Lister published his articles on the subject, I was the first to follow their example. I believe, indeed, that I am to this day the surgeon who has performed the operation of suture of the patella in a greater number of cases than any other in the world. I believe also that there are few surgeons more familiar than I with the suture of bones in general. I consider that most valuable results can be obtained from immediate suture performed antiseptically. But the question is, Does the suture of bones used as a general method for treating fractures in the way recommended by Arbuthnot Lane in England, Lambotte of Antwerp, Tuffier of Paris, and many other surgeons, deserve to be generalised and preferred to every other method? Without denying its conspicuous advantages, I must say that for my part I do not think so. I believe that it is a sort of continuation of the old method of reduction and fixation of the fragments. It would seem, indeed, to be the ideal of reduction followed by immobilisation, and has, in fact, been held to be the most perfect realisation of the old precept as to the treatment of fractures. It is certain also that the more the method of mobilisation is developed the fewer will be the occasions on which immediate suture will be performed. If, as I have shown, a small amount of movement assists the process *of repair* at the site of fracture, *it is quite evident* that suture cannot be the ideal mode of treatment, for it ought, if properly performed, to do away with all movement of the fragments. I can at once give a practical example of this; suture of the olecranon is undoubtedly the simplest of all operations of the kind. I have done it for old fractures inadequately treated by other surgeons. I have never had occasion to do it for recent fractures properly treated by my method, because perfect recovery is obtained within a fortnight without operation.

RADIOGRAPHY.

Since I began the treatment of fractures by movement, light has been thrown on the study and the treatment of fractures from another new and important source; this is the application of radiography to the examination and to the treatment of fractures. Although I am the author of an essay on the errors of radiography, I appreciate the import*ance of radiography in regard to fractures; but I hold* that on the one hand radiography cannot dispense us from the study of the symptoms of fractures, and on the other that it cannot warrant an untrained person replacing a doctor in making a diagnosis and in treating fractures. Radiography gives us only a picture of the projection of a bone, and is subject, therefore, to many more drawbacks than ordinary photography by reflection. Consequently it is necessary very critically to examine images which *for a multitude of reasons may give misleading pictures* of the site of the fracture. It is necessary to learn how to appreciate the real value of a radiogram; only after much experience can one become a good judge of radiograms of fractures, even when these radiograms have been well taken. A radiogram which is badly taken may give rise to a multitude of errors of representation which ought to be known and which produce many mistaken ideas in the mind of the non-medical public. Subject to *these two reservations, radiography is a marvellous aid in the* diagnosis and in the treatment of fractures. From this time forth the surgeon ought never to fail to use it whenever it is possible to do so. Nevertheless, the value of the help it can give varies very much. In the immense majority of cases there is very little chance that abstention from resort to radiography will prevent us from arriving at a correct diagnosis and the institution of proper treatment; it is essentially necessary in rare cases only. In the majority of instances it is only an additional security, giving a useful assurance to us and to the friends of the injured person an interesting demonstration and a document for future use.

Radiography has afforded me very special help in all that concerns my own standpoint with regard to the treatment of fractures. I have long maintained that surgeons who supposed that in reducing fractures they adjusted the bony fragments end to end and restored them to their normal position were deceiving themselves, and that in spite of faulty position, in spite of a certain degree of persistent overriding, the function of the limb again became perfect. The object which we must have in view in treatment, then, must not be this ideal juxtaposition. Radiography has, in fact, surprised surgeons very much by showing them fractures well and soundly cured, with excellent functional results, but with considerable bony displacement. Very often, indeed, surgeons not fully acquainted with these matters, and still more patients, on examining such radiograms have been led to believe that errors have been made, even when the function of the limb is as perfect as the *nature of the injury renders possible. What we are thus* taught will prove very valuable in establishing a modern treatment of fractures.

THE MODERN METHOD.

After this very short summary of the history of the treatment of fractures down to the present day, let me next explain my conception of what this treatment by movement is, and state the new facts observed by me which give a *revolutionary character to my method. A certain amount of* movement between the fragments ensures the best bony repair; this is the corner-stone on which my method is based. Every movement which is not injurious by reason of its amplitude favours repair, but it must be understood that the movement must be measured—dosed, so to say. The movement which is necessary for the repair of the bones is not less necessary to the vitality of all the constituent parts of the limb, and particularly for all the organs of motion—*joints, muscles, ligaments,* and tendons. *The relation which* the movements have to pain experienced by the patient is not such as is commonly believed; certain kinds of movement help to relieve the pain. Immobilisation, which seems to relieve, only gives momentary relief, for it prepares the way for other pains in the future. Mobilisation, gently performed as early as possible after the injury to the bones, is the method which best promotes disappearance of the pain. Massage affords the best form of movement. By simple mobilisation, by massage, and even by his own examination, the surgeon ought never to cause pain, for the pain so caused leads to fresh pain and produces complications.

The reduction of a fracture is only a relative necessity; it should be resorted to only in certain deformations of the axis of the bone which are incompatible with the function of the limb—lower third of the leg, shaft of the humerus. In a large number of cases the manœuvre of reduction is useless; *it is useless in all fractures of the radius* with impaction and moderate deformity, in most fractures of the upper extremity of the humerus, and in the great majority of fractures of the neck of the femur. In all fractures in which the displacement is due to muscular contraction any attempt at reduction is useless, as in fracture of the clavicle, of the olecranon, and many fractures of the malleoli. After massage the fracture is either spontaneously reduced, as in the case of the olecranon, or is very easy to maintain reduced, as in the case *of the clavicle and malleolus.* Those conditions which favour the vitality of the limb are all more important than those which produce immobilisation of the fragments. The fact that shortening has not the injurious influence on repair which it is said to have should not be lost sight of when considering displacement. A moderate degree of shortening which does not change the static position of a limb is favourable to repair. The muscles surrounding a shortened lever act more rapidly and better than upon a lever on which they are stretched. A certain amount of shortening ought not to be interfered with, as it is favourable to the repair of a broken bone. Massage has so great an effect in stimulating bony secretion at the site of fracture that in children, in whom the activity of the production of bone is great, massage ought not to be applied, save with great moderation, for fear of provoking excessive osseous secretion—in fact, a tumour. In their case simple mobilisation is often sufficient. Mobilisation from the beginning, within the first 24 or 48 hours, is of capital importance, and at this stage movements of very small amplitude are sufficient; passive or induced movements are *the best at the beginning*. *Active or spontaneous movements* ought to be measured and directed by the surgeon; to allow the patient to follow his own fancy with regard to active movements is dangerous—all the more dangerous because with my method the pain caused by movement disappears from the beginning, and therefore does not limit the untimely action of voluntary movement. The pain experienced and the degree of sensitiveness of the callus are the best guides in directing and in permitting movement by the patient. The secondary treatment of fractures and their supervision ought to be prolonged. Functional use of a fractured limb is the condition most favourable to its regaining active power. Even during this secondary period everything likely to irritate the region of the callus ought to be avoided. It is useless to cause pain by movements exaggerated in amplitude or by resort to forcible manipulation.

While before my investigations the surgeon contented himself, after having reduced a fracture, by awaiting cure, the modern surgeon should play a much more active, much more personal, and much less simple part. He ought not only to diagnose the fracture but ought to make its exact nature visible by a radiographic picture, and then take action to obtain not only solidity of the limb but also to restore its suppleness, its regularity of action, and its power. He must not merely await the solidification of the skeleton. Moreover, his treatment must vary a great deal according to the age, the sex, the variety in the site of the fracture, the kind of fracture of the limb, the general or local health of the patient, his occupation, and according also to the circumstances under which he is called upon to act, for if he cannot ensure proper personal supervision of mobilisation, massage, and the supervision of the movements, it may happen that he will be compelled to replace an excellent method of mobilisation by a moderately good method of suture or absolute immobilisation. The surgeon needs a great deal of experience to conduct the treatment of a fracture in the best way, and I cannot help asking with some anxiety how a non-medical tribunal is to form a judgment on questions so complex should the patient and his medical attendants cease to be in accord. The situation is complicated. Well-to-do people bring actions against surgeons because they continue to experience pain or stiffness after a fracture; workmen reproach the surgeon because he cures them too well, inasmuch as by causing the disappearance of all secondary pain, accidents are not followed by the permanent infirmity for which they hoped. The whole history of the surgery of fractures cannot be related in an address which is already too long, but I shall have succeeded in my purpose if I have made plain to you to how great an extent the duty of the surgeon has become, difficult indeed, but effective in this matter of fractures. Instead of waiting for the injured person to cure himself, we can cure him and quickly restore to him the use of his limb.

It is a laborious task, more difficult than the banal application of irremoveable appliances; it is still insufficiently understood by the profession, and altogether unknown to the *public*. *But I am proud to think that in your country* it has met so favourable a reception that you have been willing to listen to the exposition of the subject which I have to-day offered to you as a tribute of fraternal homage.

A CANCER CRUSADE IN RUSSIA.—The annual meeting of the Anti-Cancer Association was held in St. Petersburg on May 16th, under the presidency of Dr. G. E. Kein, who stated that every sixth death in St. Petersburg of persons over 54 years of age was from cancer. The first branch of the association has been established at Yalta. A cancer laboratory has been opened in St. Petersburg, as has been already announced in our columns. A special committee is endeavouring now to obtain funds to found a cancer hospital, and thereafter a Pan-Russian Cancer Institute. A special census of cancer cases in St. Petersburg will be made in 1910.

ABSTRACT OF

An Address

ON

THE DIAGNOSIS OF SYPHILITIC DISEASES OF THE NERVOUS SYSTEM.

Delivered at the Clinical and Pathological Section of the Birmingham Branch of the British Medical Association on April 30th, 1909,

BY F. W. MOTT, M.D. LOND., F.R.C.P. LOND., F.R.S.,

PHYSICIAN TO CHARING CROSS HOSPITAL; PATHOLOGIST TO THE LONDON COUNTY ASYLUMS.

GENTLEMEN,—Although syphilis is directly or indirectly responsible for a large number of organic diseases of the nervous system and it is a useful practice based upon the results of experience to treat a large number of cases of disease of the nervous system by antisyphilitic remedies, yet it is well to bear in mind that in such a widespread disease as syphilis, *coincidence* as well as *cause* is of very frequent occurrence. Therefore, in making a diagnosis the question has to be determined whether the fact that the patient has had syphilis, or even presents at the time of examination signs of active syphilitic lesions, is a coincidence or bears a direct or indirect causal relationship to the nervous symptoms for which he is consulting you. In many cases, *especially in* women, there may be no history of syphilitic infection and no signs on the body, and yet the character of the disease may clearly point to the possibility or *even the certainty* that it is of syphilitic origin; or it may happen that without a history or signs of syphilis a nervous affection may arise in an individual, which after antisyphilitic treatment ends by cure, arrest, or amelioration, but it does not necessarily follow that the disease was syphilitic, for we do not know what would have happened in the way of improvement if no drugs had been administered; in fact, we cannot be sure whether it was an example of *coincidence* or *cause*.

A person suffering from an affection of the nervous system, whose blood gives a positive antigen reaction, is much more likely to be suffering from a syphilitic affection than one who has had syphilis but whose blood does not yield the reaction, for it is an indication that the syphilitic virus is still active, and therefore capable of producing true syphilitic lesions of the nervous system. An examination of the cerebro-spinal fluid in such a case will afford most valuable evidence not only as to whether the disease of the nervous system is post-syphilitic or not, but whether it is one of true syphilitic inflammation or of a degenerative parasyphilitic nature. Such evidence is of vital importance, for in the case of the former mercury, rapidly but judiciously administered, may be followed by a complete cure, whereas in the latter it will do more harm than good. I will cite a case that was recently under my care.

A woman, aged 34 years, was admitted to Charing Cross Hospital said to be suffering from tabes. She had shooting pains in the legs, unsteadiness in gait and station, a feeling of the soles as if walking on cork, unequal pupils which reacted sluggishly to [illegible] modation, [illegible] pain and cramp in the muscles of the legs, [illegible] anæsthesia on the legs, and a belt of tho [illegible] sensation. After inquiring into the histo [illegible] suffered with headache and squint, that the knee-jerks absent on admission had returned a few days later, I came to the conclusion that this woman, with a probable duration of infection of not more than four years, was suffering really from pseudo tabes, the result of syphilitic meningitis, especially as she told me that she had had a little stiffness in the neck, and I then obtained *Kernig's sign*. Lumbar puncture was performed, and 390 lymphocytes per cubic millimetre were found—an enormous number for tabes dorsalis. This large number of lymphocytes could only be accounted for by a widespread active gummatous change in the meninges. She was placed on mercurial inunction. The symptoms began to clear up rapidly and a fortnight later the lymphocytes had fallen to 70 per cubic millimetre, and the fluid this time was tested by the Wassermann method, and found to give a negative reaction for both antigen and antibody. Unfortunately, the blood was not tested on this or future occasions. A fortnight later the cerebro-spinal fluid was examined and only 20 lymphocytes per cubic millimetre found, the patient being almost well. A fortnight later still, there were no lymphocytes, and the fluid was negative to the Wassermann reaction. The patient was quite well; the pains, anæsthesia, and unsteadiness had entirely disappeared.

It is of the greatest importance, therefore, to be able to decide whether a syphilitic patient is suffering from the immediate effects of the syphilitic virus on the enclosing, supporting, and vascular structures with *secondary effects* on the nervous structures, or from the remote effects of the syphilitic poison upon the bio-chemical stability, and, therefore, durability of the nervous elements themselves. The sooner the nervous affection follows the primary infection the more likely it is to be syphilis of the nervous system; *the longer the interval the more likely it is to be parasyphilis*, but exceptions occur, especially to the former rule. It is much more common for tertiary syphilitic lesions of the nervous system to arise very long after the primary infection than for tabes dorsalis or general paralysis to occur within a few years of infection.' There is no period from the appearance of the primary sore onwards to the end of life in which true syphilitic lesions of the nervous system may not occur. It is very unusual for a generalised syphilitic meningitis to commence after the lapse of five years from primary infection; quite one half of the cases manifest symptoms within the first 18 months, in some the symptoms are obvious with the appearance of the roseolar rash, and a few cases have occurred when the primary sore was yet unhealed—a very different order of things to tabes dorsalis and general paralysis, for in these diseases it is very rarely that symptoms occur in less than four years after infection, and the average time is ten years.

In the case of active syphilitic meningitis, arteritis, and gummata, all of which conditions may occur simultaneously, successively, or progressively over the whole cerebro-spinal axis, the blood will most probably give a positive antigen reaction, *the cerebro-spinal fluid will exhibit a great increase* of lymphocytes and albumin, but it may give neither antigen nor antibody reaction. The administration of mercury will cause the disappearance of the antigen serum reaction, the disappearance of the lymphocytes from the cerebro-spinal fluid, and the cure, amelioration, or arrest of the symptoms if the disease has not been allowed to progress so far as to lead to thrombosis of vessels and destructive ischæmic softening of the cerebro-spinal nervous substance. In the case of para-syphilis, especially general paralysis, there is a different reaction: the blood serum gives the antibody reaction; the cerebro-spinal fluid both in tabes and general paralysis exhibits lymphocytes and shows the presence of albumin.

CLINICAL DIAGNOSIS.

Neurasthenia.—A neurasthenic, who has had syphilis, and who is suffering with irritability of temper, headache, insomnia, lassitude, loss of memory, who has occasionally difficulty in finding words to express his thoughts, complaining of migrainous or vertiginous attacks and of various cutaneous sensory disturbances, in the form of anæsthesia or paræsthesia, who is hypochondriacal and depressed, who has a mortal dread of softening of the brain, from which some friend of like habits and history has suffered, whose knee-jerks are exaggerated, and whose physiognomy exhibits a wearied, hypotonic, anxious condition, with lack-lustre eyes, will naturally arouse in the mind of the practitioner the possibility of the patient being in the prodromal stage of general paralysis. Examination of the pupils and of the cerebro-spinal fluid with negative results, in conjunction with the absence of any signs of dementia, will usually enable him to decide in favour of neurasthenia and give a favourable prognosis.

[illegible] Pseudo general paralysis (diffuse [illegible] termed *syphilitic* [illegible] unfortunate term [illegible] philitic origin and [illegible]. Diffuse syphilitic brain disease is not a primary neuronic decay, but a widespread chronic inflammatory process affecting the enclosing, supporting, and nutrient structures, due directly to the action of the syphilitic virus; instead of occurring, as a rule, many years after infection, the most serious cases commence within the first four years after infection, therefore the average age incidence is some years below that of general paralysis. The early diagnosis of *diffuse cerebral syphilis* is of the most vital importance, for it is amenable to antisyphilitic treatment, which if adopted in its early stages arrests or ameliorates, and occasionally, but rarely, a cure may be hoped for. It is therefore essential to know what are the diagnostic differences of general paralysis and diffuse cerebral syphilis. It is rarely that true general paralysis is associated with permanent coarse obtrusive paralyses; in fact, the term "paresis" expresses the condition more truly. *On the other hand, diffuse syphilitic brain disease is very* liable to be followed by paralyses of all kinds.

[Dr. Mott [illegible] *of this* form of de[illegible] general paralysis. [illegible]

The dementia of syphilitic brain disease is partial; it is unequal and elective in its attack, it compromises certain forms of psychic activity, memory, association of ideas, energy and capacity for mental work, rather than diminishing intelligence as a whole. It does not alter so profoundly the character and personality of the individual, nor in *the great majority of cases does it destroy the patient's idea of his past* and present state, nor that of orientation in time and space. He still possesses the *auto-critical* faculty, and is more or less conscious of and disturbed by his mental deficiency. The accompanying bodily troubles are coarse and obtrusive and due to focal disseminated lesions in the brain and spinal cord, causing apoplectic and epileptiform seizures, as well as various paralyses and sensory troubles. The evolution of general paralysis is slow, insidious, and progressive towards marasmus and death. Syphilitic dementia, especially if it be treated [illegible] in a state [illegible]

Art[illegible] rtant factor in the production of arterio-sclerosis, especially cerebral arterio-sclerosis. Consequently a patient who has had syphilis may [illegible] which the vesse[illegible] *and kidneys* in [illegible] the blood may arise in consequence of the latter affection; owing to the renal inadequacy, and probably also the diseased conditions of the vessels of the brain, uræmic symptoms may arise in a person who is suffering with mental symptoms caused by the disease of the cerebral vessels and the altered conditions of the blood. The symptoms of uræmia—namely, headache, pyrexia, twitchings, epileptiform seizures—may simulate the symptoms and seizures of general paralysis. There are, however, points of difference which will enable a diagnosis to be made. In such a case examination of the heart and arteries and the urine would afford information. The pupils in uræmia may have a sluggish reaction to light, but they are rarely unequal or irregular. Very probably examination of the fundus will show retinitis, hæmorrhages, and arterio-sclerosis of the retinal arteries, causing thickening of the walls, which appear *like silver wires; consequently the veins as they pass* over the thickened arteries often show a kink. The patient is usually over 50 years of age. The cerebral symptoms are often characterised by a progressive dementia and paralysis, but there are many points of difference, both in the mental and motor symptoms.

[Dr. Mott here said that the dementia of cerebral arterio-sclerosis was a partial, unequal loss of mind. The patient became irritable, suspicious, and even dangerous to himself and others, but, unlike a general paralytic, he retained his notions of personality and the faculty of auto-criticism, and was more or less conscious of his loss of memory and mental enfeeblement.]

Chronic alcoholism.—C[illegible] in which there is a history or si[illegible] difficulties in the matt[illegible] reasons: first, because [illegible] *the disease take to drink. The symptoms they present* are largely due to the effects of the intoxicant, and they are certified and sent to the asylum, where the diagnosis of *mania a potu* is made. The true nature of such a case declares itself after the effects of the alcohol have had time to wear off. Hallucinations, especially of vision and of a terrifying nature, are common in alcoholism; they are not common in general paralysis uncomplicated by alcoholic intoxication. The dementia of alcoholism is characterised by the predominance of the moral affective defects over the intellectual, by a degradation of the ethical sense, deterioration of will, and the tendency to delusions of persecution, jealous suspicion, and violent motor reactions, rendering them dangerous to themselves and others. The psychic activity is confused rather than destroyed. There is deficiency rather than absence of memory.

Polyneuritic psychosis (*Korsakow's disease*).—The clinical picture of a severe case of the disease is not unlike that of general paralysis in its final stages. The patient, prostrate, bedridden, and emaciated, with contracted limbs and suffering with bedsores, lies oblivious to her surroundings; roused to reply to questions, only incoherent responses are obtained. Such a condition may well be termed *pseudo-general paralysis*. Frequently a definite diagnosis cannot be made unless the case be watched; if this be done occasionally at intervals the mind appears to be clear in Korsakow's disease. The definite signs and symptoms of polyneuritis may be present. When the symptoms of Korsakow's disease are confined to loss of memory and mental confusion the diagnosis is more difficult. Auto-criticism may still be present in the patient suffering with Korsakow's disease; consequently, when confronted by her mental shortcomings she betrays astonishment and even alarm in her facial expression. The general paralytic, having lost the faculty of auto-criticism, is self-satisfied, and the expression is one of foolish contentment or of apathetic indifference. Hogarth, in the scene of "The Rake's Progress at Bedlam," nearly one hundred years before the classical description by Bayle, portrayed the general paralytic with his grandiose delusions and lack of auto-criticism. In the picture we see the man, partly naked, seated on a stool, a paper crown on his head, a wooden sceptre in his hand, and a foolish, self-satisfied mock majestic smile on his countenance. The cerebro-spinal fluid in Korsakow's disease would be negative as regards the antibody reaction and lymphocytosis; therefore in all doubtful cases lumbar puncture should be performed and the cerebro-spinal fluid examined.

Dementia præcox.—The age, mode of onset, and evolution of this disease are unlike those of general paralysis, except the juvenile form. In 80 per cent. of the cases of dementia præcox the mental symptoms occur before the age of 25. There is usually a strong hereditary history of insanity, and no history or signs of congenital syphilis. General paralysis is a disease which, on an average, does not commence until ten years after infection; therefore the most frequent period for general paralysis to occur is not adolescence, but the prime of life. Occasionally, however, I have seen young women admitted to the asylum with dementia paralytica in whom the mental affection commenced at a relatively early age. Inquiry into the history often shows that they were prostitutes or had come from a refuge home, or a history of congenital syphilis was either certain or probable. Dementia is not the earliest sign of this affection, but hallucinations and fragmentary delusions; the Argyll Robertson pupil is not present, the pupils are not unequal, and, as a rule, not irregular. If there is any doubt the diagnosis can at once be settled by examination of the blood and cerebro-spinal fluid by the Noguchi and Wassermann methods, and by cyto-diagnosis of the cerebro-spinal fluid. 20 successive cases of dementia præcox were examined by Mr. G. H. Harper-Smith and Dr. G. H Rae Gibson in the laboratory, and in every instance the result was negative.

Disseminated sclerosis.—The typical insular sclerosis of young adults should not be mistaken either for general paralysis or multiple syphilitic brain disease, although cases of multiple focal patches of sclerosis, the result of syphilitic arteritis, thrombosis, and ischæmic softening, in many respects resemble that form of insular sclerosis the cause of which is at present unknown. The difference in the clinical symptoms and the evolution of the disease to general paralysis in most cases suffices for a differential diagnosis; but if there be any doubt, examination of the cerebro-spinal fluid and blood with negative results will serve to exclude general paralysis.

Cerebral tumours.—Cerebral tumours without motor or sensory troubles are not infrequently sent to asylums and, according to my experience, they are as often as not called "general paralytics." Examination of the fundi in most cases would have revealed optic neuritis, a condition never found in general paralysis, although it may occur in syphilitic brain disease; but as a rule, according to my experience, syphilitic gummata and syphilitic meningitis do not produce the same degree of swelling of the disc that non-syphilitic tumours do; very much, however, depends upon the situation and the rapidity of growth of the tumour. Large slow-growing tumours of the frontal lobe occurring in men at the prime of life, and with a [illegible] drink, may be especially difficult to [illegible] slow demential form of general paralysis; especially is this so when the tumour destroys the left frontal lobe and irritates the adjacent motor cortex, as it would cause speech affections from the involvement of Broca's convolution and epileptiform seizures. I saw recently a woman in one of the London County Asylums and had her transferred to Charing Cross Hospital. Mr. E. T. Collins found five diopters of swelling in each disc. After a course of mercurial treatment the swelling went down rapidly to two diopters, and from being unable to read large print, she could read quite small print, the headache ceased, and the vomiting no longer occurred. The cerebro-spinal fluid of this case did not give the Wassermann reaction, although it contained a considerable excess of lymphocytes; but then we know that in only about 25 per cent. of cases of syphilitic brain disease does the cerebro-spinal fluid give a positive antibody result. [Dr. Mott here said that lymphocytosis by itself was not sufficient evidence to prove that the disease was syphilitic, but the result of treatment combined with this made it fairly certain that it was a syphilitic gumma that caused the symptoms in this case.]

EXAMINATION OF THE CEREBRO-SPINAL FLUID.

The Wassermann-Neisser-Brück method.—This test may be carried out in the following manner. It is necessary first to immunise an animal against the blood corpuscles of some other animal—for example, by injecting the blood corpuscles of an ox into the circulation of a rabbit. After several injections the blood serum of the rabbit becomes hæmolytic to the blood corpuscles of the ox by virtue of the presence in the serum of an immune body *plus* the normal complement or cytase. The latter is removed from the serum after withdrawal from the rabbit by heating to 56° C. for 30 minutes. There is then left in the rabbit's serum the immune body, which by itself will not dissolve the red blood corpuscles of the ox. The addition, however, of a small amount of guinea-pig serum which contains complement will at once restore its hæmolytic properties. The actual experiment consists in mixing the serum or cerebro-spinal fluid to be examined in varying dilutions with a watery or alcoholic solution of the liver of a syphilitic fœtus; a small amount of the serum of a guinea-pig is added, and the bulk made up to a constant volume (about two cubic centimetres) with saline solution. The series of tubes containing these mixed solutions are placed in an incubator at 37° C. for one hour, and then the sensitised corpuscles are added. By sensitised corpuscles I mean the washed corpuscles of the ox to which has been added the heated rabbit's serum. The mixtures are again placed in an incubator for two hours at 37° C., then removed and placed on ice over night. The next morning the amount of hæmolysis in each tube can be estimated. If, on the one hand, antigen (contained in the extract of the syphilitic liver) and antibody (in the serum or cerebro-spinal fluid) have been present they have united with the complement (provided by the guinea-pig serum), and no solution of the corpuscles will have taken place, because the complement has been fixed before the addition of the sensitised corpuscles. If, on the other hand, the antibody was not present in the serum or cerebro-spinal fluid, then the complement in the guinea-pig serum has remained free to act on the sensitised corpuscles and to lead to their solution (hæmolysis). A control experiment using normal serum or cerebro-spinal fluid—namely, one which contains no antibody—must be made at the same time. In order to make the *antigen* test, the blood serum or cerebro-spinal fluid is used in place of the syphilitic liver extract, and tested in varying dilutions against a serum or cerebro-spinal fluid which has previously been proved to contain antibody in known amount.

The Noguchi method.—A simple method introduced by Noguchi consists in boiling two parts of the cerebro-spinal fluid with five parts of a 10 per cent. solution of butyric acid in saline solution for a few seconds and then adding one part of a normal sodium hydrate solution and again boiling briefly. A flocculent or granular precipitate is obtained on standing in parasyphilitic affections due to the presence of a globulin. The test is useful in distinguishing general paralysis from other forms of insanity not associated with meningo-encephalitis.

Cyto-diagnosis.—The number of leucocytes present in the cerebro-spinal fluid may be estimated approximately by the following methods. 1. A drop of the fluid which has been previously well shaken is placed in the chamber of a Thoma-Zeiss hæmocytometer and the cells allowed to settle. The number of cells lying over the 400 squares of the chamber multiplied by 10 will give the number of leucocytes in one cubic millimetre of the fluid. 2. The cerebro-spinal fluid is centrifuged and the supernatant fluid poured off. The residue is removed in a capillary pipette, blown on to a slide, and allowed to dry. Stained with Leishman or Jenner's stain the residue from a normal cerebro-spinal fluid will show at the most only two or three lymphocytes in the field with a magnification of 400 diameters, whereas in progressive para-syphilitic affections the lymphocytes are markedly increased in number.

An Address

ON

THE OPERATIVE TREATMENT OF FRACTURES.

Delivered before the American Medical Association, Atlantic City, New Jersey, U.S.A., on June 9th, 1909,

BY W. ARBUTHNOT LANE, M.S. LOND.,
F.R.C.S. ENG.,

SURGEON TO GUY'S HOSPITAL; SENIOR SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

GENTLEMEN,—I hope to put before you clearly and briefly my views and experience of the treatment of simple fractures.

I was originally led to resort to operative procedures by finding from the dissection of bodies, whose bones had sustained fractures that the fragments when displaced had hardly ever united in anything approaching accurate apposition, and that definite changes took place in those joints whose functions were affected by the alteration in the physiology of the skeleton resulting from such imperfect replacement of the broken fragments.

A careful inquiry into the results of the treatment of fractures by splints and manipulation confirmed the experiences of the dissecting-room, and showed that the consequent joint changes meant depreciation in physique and in the wage-earning capacity of those who had to engage in laborious pursuits. These views met with violent opposition till the discovery of x rays proved that the first contention was true, while the law courts are steadily impressing on the profession in a costly manner the disabilities which are associated with imperfect restoration in the form of broken bones.

In 1894 I read before the Clinical Society of London my first paper on the results of the treatment of simple fractures by operation, and I contrasted them with those obtained by other means. Since that time I have continued to operate on all simple fractures in which I was unable to bring the fragments into satisfactory opposition when the circumstances of the patient required it. During the last 17 years I have operated upon a very large number of recent fractures at all ages, from early infancy to extreme old age, with [illegible] oyed various methods [illegible] e means of fixation of [illegible] which shall be at [illegible] application. I soon [illegible] pen operation was to become general it was necessary that the procedure should be rendered as uncomplicated as possible.

The difficulty that has beset this treatment is that if a foreign body is left in a [illegible] more careful about asep[illegible] of events, and in a deg[illegible] foreign body. Judging from what I have read on the subject it would also appear that the methods of the antiseptic surgeon, as contrasted with those of the surgeon who [illegible] It is because of [illegible] ne extent from a [illegible], screws, &c., that we hear so many complaints of the development of rarefying osteitis, about a screw or wire perforating a bone, of screws working loose and consequently becoming ineffective for the purpose for which they were employed, and of the employment of such futile methods as ivory pegs, &c. With the exercise of greater cleanliness and with an increasing manual dexterity these troubles will cease to arise. Why a surgeon should not be governed by the same principles by which an ordinary skilled mechanic works I cannot understand, but I presume that the surgeon has rarely had any such training as would fit him for this kind of work Curiously enough, the opposition to such operative procedures, which continued with such intensity for so long, seems to have suddenly diminished because several surgeons have broken loose from tradition and have satisfied themselves that by operation alone can the greatest measure of success be obtained.

I do not propose to discuss the various methods which I have adopted for retaining the fragments immoveably in accurate apposition, but will confine myself to describing those which I now find most effective for the purpose.

The locality of the incision should be carefully chosen to avoid damage to important structures, and especially to nerves, and to reduce to a minimum the chance of subsequent infection of the wound. In the lower extremity there is no risk of danger to important vessels, tendons, or nerves, but in the arm the conditions are very different and every precaution must be taken.

To ensure asepsis, which one can do with certainty, an incision [illegible] and heavy enough to fall away from the wound and do not require to be held. The forceps used to control hæmorrhage exert pressure upon the bleeding vessels sufficient to permanently obliterate their lumen. By their use the necessity of the introduction of the gloved hand into the wound for the purpose of tying a ligature is avoided. The danger of the rubber glove is the possible presence of a puncture through which infection might enter the wound. The hæmostatic forceps are very long, so that the handles fall free of the wound. All instruments employed for manipulating fragments, holding swabs, plates, and screws, drilling bones, and driving in screws are also very long and very powerful in order to avoid any contact of the portion of the instrument grasped by the hand with the wound, since the gloves are liable to be damaged in the powerful manual efforts which are sometimes necessary to restore the broken bone to its original form.

In considering the means by which accurate apposition of fragments is effected we must take into account the nature of the fracture and whether one or two bones are involved. Besides this, comminution often adds greatly to the difficulty of the operation. In torsion fractures the surgeon must remember that in proportion to the overlapping of the fragments so there exists between and separating the surfaces which have to be brought into apposition an increasing quantity of muscle, since the chisel-shaped fragments diverge from one another as they overlap, burying themselves in the surrounding soft parts. Anyone imbued with the old creed and unfamiliar with operations on recent fractures would imagine that to effect apposition all that is necessary is to exert traction upon the distal fragment of the broken bone by pulling on the limb, the trunk being secured, and that by means of this traction the fragments can be drawn from their beds in the soft parts and the fractured surfaces placed in accurate contact. In the case of spiral fractures of the long bones of the lower extremity, in which this variety of fracture is the most common, no amount of traction which can be exerted on the limb is sufficient to overcome the overriding of the fragments. This is due to the resistance offered by the bruised and swollen soft parts which surround the fractured bone and from the point of view of traction on the limb form inextensile ties in its length. This applies equally to fractures produced by direct injury, the resistance to replacement varying with the extent of overlapping of the fragments, the amount of extravasation of blood, the laceration of soft parts, and the consequent inflammation.

To effect apposition in the spiral fracture it is necessary to divide or displace all soft parts intervening between the fragments, to carefully clean away any clot or soft tissues from the fractured surfaces, and especially from the retreating angles of the fragments, and to exert traction on the limb, supplementing that traction by forcible apposition of the fragments by powerful forceps, which are so manipulated as to glide the inclined plane of one fragment upon the other. This gliding of the fragments is facilitated by the introduction of a narrow flat blade with a serrated edge to prevent it slipping between the fragments which when rotated upon its axis by its powerful leverage action moves the fragments held together by the forceps upon one another.

In the case of a fracture of a single bone as the femur which has been broken by direct injury, the extent of the overlapping of the fragments is, from the nature of the injury and the mode of causation of the fracture, usually much less. Still the damage sustained by the surrounding soft parts or ties in the length is correspondingly greater, since in the torsion fracture the injury which the muscles sustain results solely from the fracture, while in that produced by direct injury the soft parts are lacerated and bruised by the impact of the force which determined the fracture and only to a small extent from the forcible displacement and overlapping of the fragments.

In a fracture of the femur produced by direct injury traction alone exerted on the limb does not appear to influence the overriding of the fragments. The fragments can most readily be brought into apposition by so manipulating the limb that the extremities of both fragments are made to protrude through the incision, and can be manipulated till the inner margins of the fractured surfaces are brought in contact with one another. Each fragment is grasped with forceps, and while the limb is slowly and steadily extended the opposing edges of the ends of the fragments are levered on one another till the broken surfaces come into accurate apposition, when the axes of the fragments are in continuity and the bone is restored to its normal form. This difficulty does not exist to the same extent in fractures of the upper extremity produced by direct injury, since the ties in this limb are less bulky and tense than in the leg, and from the nature of things spiral or torsion fractures are of comparatively rare occurrence in the humerus, radius, or ulna, though they are not infrequent in the metacarpals.

The difficulty of effecting accurate apposition is very greatly increased by the presence of comminution which can make a considerable demand on the skill and ingenuity of the surgeon. This complication produces most obstacles in the case of the spiral fractures, since every aspect of the fragments is very oblique and much is necessarily out of sight, and there is no surface or point on which one fragment may be made to impact on the other. Perhaps the most awkward complication one may have to meet is great fragility of the fragments, such as appears to exist to a great extent in alcoholics and to a lesser degree in feeble children and in old age, but this concerns the retention of the fragments in apposition rather than their reduction.

Delay in operating renders the replacement of the fragments more difficult, because the shortened soft parts or ties become rapidly less extensile, and a correspondingly greater force is required to stretch them. This is a serious matter if the bones are fragile or comminuted. The operation should be undertaken as soon as the skin can be effectually cleansed.

As to the best means of retaining fragments securely in apposition when the fractured bone has been restored to its normal form, I would point out that in certain fractures, as in those about epiphysial lines, there is usually no tendency to a recurrence of the displacement once reduction has been effected, providing the part is put up in a position the reverse of that in which it was produced. For instance, in a Colles's fracture either through bone or through the junction of the shaft with the epiphysial line, after replacement of the fragment by manipulation or operation the hand is retained in a position of extreme flexion and adduction, which is also the extreme position of usefulness. It is well to remember that if the surgeon has to employ any means for retaining an epiphysis in position—as, for example, in separation of the lower epiphysis of the femur—he should insist on the removal of the rigid connecting medium after union has been effected; otherwise it will control the growth in the epiphysial line and deformity will result. In a case of a complicated fracture through the inner half of the epiphysial line of the lower end of the femur, objection was made to the removal of the staples which were employed to retain the fragment in position because of the condition of the patient. Later this patient developed a bowed leg.

There are occasions on which it is necessary to rely on screws alone, as in the case of fractures of the neck of the femur and in some spiral fractures, but in the vast majority of cases I prefer to use as long and as strong a steel plate as possible, carrying as many screws as space permits. To reduce the difficulty of finding the drill-hole in the distal compact layer of bone, which is frequently of no avail when the fragment is comminuted, I employ screws of a length only sufficient to engage the proximal compact tissue and threaded up to the head in order to secure as firm a hold as possible on the bone. For this purpose I use screws in two lengths—½- and ⅝-inch—and in two gauges—Nos. 5 and 7. In the young infant I employ ⅜- and ½-inch screws in No. 3 gauge. The fewer the varieties of screws employed the smaller is the number of drills, and consequently the less complicated the operation, since each gauge of these modified screws requires only one drill. By this means I have reduced enormously the difficulties of securing the fragments immoveably in apposition. In simple fractures I hardly ever use wire. I would exclude from this the fractures of infancy when two or more weeks have been allowed to elapse between the receipt of the injury and the operation. In such cases the distal fragment loses its density at a very early period, and while the proximal fragment will hold the screw securely the thread will get no secure grip of the distal portion because of its friability. In these circumstances I supplement the junction by encircling the plate and distal fragment with a loop of silver wire.

The operative measures which are required in the treatment of badly united fractures are similar, except that the fragments have to be cut through in two distinct planes in fracture of a single bone and in four planes in fracture of two bones, such as the radius and ulna or tibia and fibula, in order that the axes of the fragments can be rendered continuous. These operations are very much more difficult and are accompanied with more risk from hæmorrhage than are recent fractures. The results obtained are also very rarely as good because of the changes which develop in the joints whose functions have been affected by the faulty junction. I think that with better initial treatment such cases will soon cease to exist.

Whatever the extent of the shortening in badly united fractures, the surgeon should endeavour to correct it entirely or to reduce it as much as possible. There is, as far as I am aware, no limit to which the muscles, nerves, vessels, &c., can be stretched if only sufficient force can be exerted on the fragments. Such operations may make a very great demand on the skill and resources of the surgeon, and an increasing familiarity with them will enable him to obtain an increasing measure of success.

A PRELIMINARY NOTE ON THE VACCINE-THERAPY OF ENTERIC FEVER

BY D. SEMPLE, M.D., M.CH.R.U.I., D.P.H. CANTAB.,
LIEUTENANT-COLONEL, R.A.M.C. (RETIRED), DIRECTOR, CENTRAL RESEARCH INSTITUTE FOR INDIA, KASAULI, PUNJAB, INDIA

MY attention was first drawn to the possibility of using a bacterial vaccine in the treatment of enteric fever from a remark made by Sir A. E. Wright in a lecture given by him under the auspices of the Chelsea Clinical Society, London, and reported in the *Clinical Journal* of May 6th, 1906. Wright suggested that the results obtained by M. Chantemesse in exploiting an antityphoid serum were probably due to a typhoid vaccine in disguise; or in other words, that the antiserum used probably contained bacterial elements derived from the cultures originally injected into the horses which supplied the serum.

The subject of vaccine-therapy in cases of enteric fever was referred to by Lieutenant-Colonel C. Birt, R.A.M.C., in an article by him in the *Journal of the Royal Army Medical Corps* for September, 1906. Birt in his review recommended the inoculation of one-fiftieth of the dose of vaccine used in preventive inoculations, and that the blood changes should be studied either by opsonic index determination or by Bordet's and Gengou's reaction of fixation of complement. He also advised that the site of injections should vary; no part should be twice inoculated. He did not record any cases treated by himself, but mentioned that C. Fraenkel had treated some 57 cases as long ago as 1893.

The therapeutic application of this method to the treatment of enteric fever is as yet practically unexploited, but judging from the results obtained in the few cases which I have treated, the method is worthy of careful consideration, and may possibly be the means of greatly diminishing the death-rate from this disease.

The principle [illegible] lactic bacterial [illegible] This principle [illegible] which elaborates [illegible] therapy one of the most important points connected with the elaboration of these immune bodies is that it should take place before marked necrotic changes have taken place in [illegible] important. Our aim should be to follow up the positive phase response without calling into existence any perceptible negative phase. It is very evident that we are not likely to attain this object by using large doses, or even moderately large doses, giving rise to marked constitutional symptoms and a consequent negative phase superimposed upon the disease from which the patient is already suffering; we are more likely to attain our object by using small doses of a vaccine prepared from the strain of bacteria responsible for the patient's disease, and only just sufficient to produce a response without producing any registrable negative phase. When the dose is regulated on these lines a positive phase only is registered, and a phagocytic response takes place soon after the inoculation.

Wright[1] obtained evidence of increased bactericidal power in the blood of persons inoculated with an antityphoid vaccine on the day following inoculation; also evidence of increased phagocytic response on the day following the inoculation of a staphylococcus vaccine. In numerous cases he obtained evidence of an increased opsonic power of the blood within one hour after the inoculation of a tubercle vaccine. Allen[2] has in several instances obtained an increased opsonic index within 24 hours after the inoculation of bacterial vaccines; and in one case, after the therapeutic inoculation of 250,000,000 organisms prepared from a culture of the micrococcus catarrhalis, he obtained an opsonic index of 1·57 within eight hours; and indices of 2, 2·23, and 2·32 within 12, 15, and 18 hours respectively. It is true that in these examples of a quick response the causal micro-organisms are more or less localised, and to some extent shut off from free access to the lymph and blood streams, and it is in cases of this kind that bacterial vaccines are believed to give the best results; but latterly several successful results have been recorded by Wright and others in cases of streptococcal septicæmias.

Typhoid fever being a general septicæmia in addition to having localised foci when the causal micro-organisms multiply, there are no *à priori* reasons why the principles of curative vaccination, which have been successfully applied to other septicæmic diseases and localised infections, should not hold good in this disease. The conditions which obtain in a case of enteric fever are not favourable for the rapid production of protective substances, because the specific bacterial elements are being constantly introduced into the blood stream, where they are killed off and diluted to such an extent that when they come in contact with the tissues which elaborate bacteriotropic substances a feeble response only can take place. In these circumstances a toxic effect may be the most prominent symptom, and as a matter of fact, it often is in many cases of enteric fever.

When the same bacterial elements are introduced subcutaneously in the form of a vaccine and in appropriate doses the toxic effects are a negligible quantity, and mainly localised to the vicinity of the inoculation. The bacterial elements are brought directly in contact with the tissues which respond by the elaboration of protective substances. An increase of thermostable opsonins may be taken as an index of the immunising response taking place during an attack of enteric fever, and it may also be taken as an index of the increased immunising response stimulated by the vaccine treatment of this disease.

There is at present a general consensus of opinion that autogenous vaccines give rise to better results than stock vaccines. The results achieved in the two cases (Nos. 8 and 9) treated with vaccines prepared from their own micro-organisms would seem to point towards a justification of this opinion. Of the nine cases here recorded seven were treated with a stock vaccine prepared from one strain of bacillus typhosus, and two with autogenous vaccines. The vaccines were prepared from a 48-hours' broth culture killed by the addition of 0·5 per cent. carbolic acid; standardised by counting after the dilution of a measured quantity (in accordance with methods devised by Sir A. E. Wright) and sterility tested in the usual way. It was found that the addition of 0·5 per cent. carbolic acid could be relied upon to give a sterile vaccine within 24 hours without any previous heating. This method of sterilisation is now used at the Central Research Institute, Kasauli, in the preparation of antityphoid vaccine sent out for preventive inoculations, the possible harmful effects of heating being avoided.

From a practical experience of the use of this particular strain of bacillus typhosus in prophylactic inoculations, and judging from the blood changes and reactions following its use, 0·5 cubic centimetre was found to be a suitable first dose, and 1 cubic centimetre a suitable second dose. These quantities corresponded to 270,000,000 and 540,000,000 bacilli respectively. In the therapeutic application of the vaccine it was deemed advisable to give doses not likely to cause any apparent constitutional disturbance. In the first few cases treatment was commenced by giving 6,000,000 bacilli, about a forty-fifth of the first prophylactic dose. In the other cases the doses varied from 8,000,000 to 12,000,000 bacilli, and in two cases 30,000,000 and 40,000,000 bacilli were given. The vaccine was always given in a bulk of one cubic centimetre, which was easily arrived at by diluting the original vaccine with normal salt solution, so that one cubic centimetre corresponded to the number of bacilli to be given.

The front of the chest about four inches below the centre of the clavicle was the site selected for the injections, and no two inoculations were given in exactly the same place, a practice which was based on the assumption that the bacteriotropic substances resulting from the inoculation of bacterial vaccines are probably formed in the tissues at the site of the inoculations.

The technique employed in testing the phagocytic response was practically similar to that used by Sir A. E. Wright in his opsonic experiments. It was necessary to use a diluted serum in order to obtain a more exact measure of the increase in thermostable opsonins, as indicated by an increase in the phagocytic response of those inoculated. Unless the serum had been diluted it would have been impossible to accurately count the bacilli taken up by the phagocytes in some of the cases treated.

Technique.

1. *Serum.*—Blood from the finger was drawn off into glass capsules and allowed to stand at room temperature for 24 hours, when the clear serum was pipetted off and diluted 1 in 5 with sterile normal salt solution. The diluted serum after being filled into glass pipettes and sealed was heated in a water bath at a temperature of 58° C. for 15 minutes, so as to eliminate the thermolabile opsonins and complement. It was then ready for use. The control serum was from a healthy laboratory attendant and prepared in the same way.

2. *Blood corpuscles.*—One volume of blood was drawn off from the finger of a healthy man and mixed with an equal volume of 1·5 per cent. sodium citrate in normal salt solution. The mixture was then centrifuged and the supernatant clear fluid drawn off with a pipette. The corpuscles were then well mixed with an excess of normal salt solution, and again centrifuged and the supernatant fluid drawn off. This process was repeated three times. The washed corpuscles were now gently mixed so as to give an even distribution of the white cells.

3. *Bacterial suspension.*—A platinum loopful from the surface of an 18 hours' agar growth of bacillus typhosus was well emulsified in normal salt solution and allowed to stand upright in a piece of glass tubing about a quarter of an inch in diameter, sealed at one end, and resembling a small test tube. It was allowed to stand in this position while the serum dilutions and washed corpuscles were being prepared. Care was taken to make the suspensions as nearly as possible of the same strength each time and when used one volume was drawn off from the upper part of the fluid in the tube. The same strain of bacillus typhosus was used for the opsonic and agglutination tests throughout these experiments.

4. *Dilutions employed.*—Heated serum dilution (1 in 5), two volumes; washed corpuscles, two volumes; and bacillus typhosus suspension, one volume. These proportions gave a

---

[1] Principles of Vaccine Therapy, a lecture delivered before the Harvey Society, New York, by Sir A. E. Wright.

[2] Vaccine Therapy and the Opsonic Method of Treatment, second edition, 1908 (London: H. K. Lewis).

final serum dilution of 1 in 12·5. After being well mixed by filling and refilling several times into a glass pipette the end of the pipette was sealed off and the mixture placed in the incubator for 15 minutes at a temperature of 37° C. It was then taken out of the incubator, the end of the pipette snipped off and the contents again well mixed, and films made and stained in the usual way. When counting only polymorphonuclear corpuscles were noted; a note was also made of the corpuscles which showed no phagocytosis. Some workers attach more importance to the percentage of negative corpuscles than to the phagocytic index as indicated by the average number of bacteria ingested. On this account I decided to record the results in both ways.

It is well to bear in mind that the opsonic content of an enteric fever patient's [illegible] day to day irrespective of [illegible] ormal person's opsonins may also fluctuate from day to day, but, generally speaking, they remain at a lower ebb than in the case of a patient who is successfully struggling to rid himself of a bacterial infection, or who is being assisted in his efforts to produce bacteriotropic substances by means of vaccination.

In the application of this method of treatment the guiding principles should be to avoid the production of any apparent constitutional disturbance, and to follow up the positive phase as indicated by an increase of opsonins in the patient's serum. On these points much yet remains to be observed, and further experience is required to decide the most efficient dosage and interspacing of doses.

Judging from the manner in which Cases 8 and 9 responded to the treatment I would recommend when possible a vaccine prepared from the patient's own infecting micro-organism, to be given as early in the disease as possible, and in doses of from 15,000,000 to 30,000,000 of bacilli daily, for from four to six days in succession, a fresh site to be selected for each injection, and the opsonic index to be tested daily. Any lowering of the phagocytic response or other untoward constitutional effects would indicate that benefit was not being derived from the inoculations, and in the event of this occurring an interval should be allowed to elapse until the opsonic content of the blood became increased.

The quickest method of obtaining the bacillus typhosus or paratyphosus for the preparation of an autogenous vaccine is to make a cultivation from the patient's blood. This is best done by drawing off a few cubic centimetres of blood from the median basilic vein of the arm by means of a sterile needle and syringe, using aseptic precautions, and immediately transferring the contents of the syringe to 20 or 30 cubic centimetres of Conradi's bile medium, or to the same amount of sterile ox bile. The blood-infected bile medium should be incubated for from 16 to 24 hours at 37° C., and subcultures made on to one or two agar slopes. When the agar slopes have been incubated for 24 hours at 37° C. any growth present is tested for purity, and also as to whether it is a typhoid or paratyphoid A or B growth. Having cleared up these points, a few broth tubes may be inoculated from the pure agar growth, and after 24 hours' incubation at 37° C. a vaccine can be prepared and standardised in the usual way. Counting from the time the sample of blood is taken from the patient it is possible to have a vaccine prepared by this method on the third day, or on the second day by utilising the first agar growth obtained from the bile medium.

While the autogenous vaccine is being prepared treatment should be commenced by using a stock vaccine, and then carried on with the vaccine prepared from the patient's own micro-organism as soon as possible.

Where facilities for the preparation of a vaccine from the patient's own micro-organism are not available a stock vaccine could be used. The vaccine used for the prophylactic inoculations could be diluted with sterile normal salt solution, so that one cubic centimetre contained the number of bacilli suitable for a therapeutic dose. In the absence of facilities for carrying out opsonic tests, Widal's reaction in conjunction with the general condition of the patient might be taken as guides to dosage, interspacing of doses, and the continuance of treatment. During vaccine treatment there is no necessity to alter or interfere with any ordinary symptomatic or general treatment usually carried out. In the cases here recorded the usual treatment was not in any way interfered with.

Of the 11 cases, details of which are given, nine were treated with vaccines—viz., seven with stock vaccines and two with autogenous vaccines (vaccines prepared from their own infecting micro-organisms). Two of the 11 patients did not wish for vaccine treatment. One of the untreated patients died. All those who received vaccine treatment made a good recovery. The bacillus typhosus was isolated from the blood early in the disease in every case. My thanks are due to Captain E. D. W. Greig, I.M.S., for much assistance in making cultivations from the blood, and to Captain D. S. Harvey, R.A.M.C., for valuable help in testing the opsonic index in several of the cases detailed in Appendix I.

Conclusions.

1. It will be seen that the administration of bacterial vaccines in cases of enteric fever is a practical method of increasing the bacteriotropic substances in the blood, as evidenced by an increase in the opsonic index of those treated by this method.

2. When appropriate doses are given the method is devoid of all risks, is easily carried out, produces no apparent disturbance in the patient's condition, and does not interfere with any other treatment the physician may deem necessary.

3. It would not be possible to generalise from the few cases here recorded as to whether vaccine treatment has a marked effect in cutting short the fever period. Cases 3 and 4 treated with stock vaccine, and Cases 8 and 9 treated with autogenous vaccines, would seem to indicate that it may have this effect.

4. In six of the nine cases treated well-marked improvement set in after the inoculations. This was especially the case in Nos. 8 and 9 treated with autogenous vaccines. In the remaining three there was an amelioration of the clinical symptoms.

APPENDIX I.

Details of the 11 cases of typhoid referred to in the foregoing note, showing the dates and results of (1) cultivations made from the blood: [illegible] vaccine; (3) [illegible] of the serum opsonic tests; and (4) [illegible] cillus typhosus on bacillus typhosus. I[illegible] was isolated from the blood on the first attempt. A few cubic centimetres of blood were drawn off by means of a sterile needle and syringe and under strict aseptic precautions from a vein of the arm in front of the elbow, and immediately transferred to either a small bottle or small flask containing 30 cubic centimetres of Conradi's bile medium. The blood-infected bile medium was then incubated for 24 hours at 37° C. and subcultures made on to agar slopes, with the result that a pure culture of bacillus typhosus was obtained from every case.

CASE 1. *Treated with stock vaccine*.—Private ——, aged 25 years. Total service two years. Admitted to hospital on Dec 14th, 1906. Disease, enteric fever. Dec. 17th: A cultivation made from the blood gave a pure growth of bacillus typhosus. 18th and 26th: First and second inoculations of vaccine respectively, 6,000,000 bacilli. Opsonins not tested.

Remarks.—The inoculations had no appreciable effect in diminishing the length of the fever period. Some improvement in the clinical symptoms was produced by the vaccine. About the twenty-fourth day of the disease the patient developed symptoms of bronchitis accompanied by a severe cough. At no time during the disease were the symptoms severe, and the patient made a good recovery.

CASE 7.—*Treated with stock vaccine.*—Driver ——, aged 23 years. Service four years and three months. In India 11 months. Admitted to hospital April 28th, 1908. Disease, enteric fever. April 29th: A cultivation made from the blood gave a pure growth of bacillus typhosus. May 2nd, 3rd, 4th, and 5th: First, second, third and fourth inoculations respectively of 30,000,000 bacilli.

Thermostable Opsonins.

1. *Before inoculation.*—May 1st: 50 cells = 293 bacilli, average = 5·96; negatives = 34 per cent. Remarks.—The disease was not of a severe type, although the fever period was somewhat prolonged. Patient commenced to convalesce on the thirty-third day. His opsonic index remained fairly high throughout except on April 30th and May 4th, which corresponded to the worst periods of his illness. (See Chart 6.)

APPENDIX II.

The charts here reproduced show the temperature and opsonic indices of six of the 11 cases of typhoid referred to in the foregoing note. These charts also show the date and day of disease on which the bacillus typhosus was isolated from the blood; the dosage, and interspacing of doses of vaccine in the cases treated. In the opsonic charts the control or normal person is taken as unity, although in several instances the controls were below this average standard and in others above it. The opsonic charts are intended merely to give a general impression as to the increase or decrease of opsonins during the progress of the disease. A more correct idea of the opsonic changes which took place will be found in the details of each case in *Appendix I.*

A CASE OF FACIAL PALSY TREATED BY FACIO-HYPOGLOSSAL ANASTOMOSIS,

IN WHICH AN ANASTOMOSIS WAS ALSO MADE BETWEEN THE SPINAL ACCESSORY AND THE DISTAL SEGMENT OF THE DIVIDED HYPOGLOSSAL NERVE IN ORDER TO PREVENT PERMANENT LINGUAL PARALYSIS AND ATROPHY.[1]

BY CHARLES A. BALLANCE, M.V.O., M.S. LOND.,
SURGEON TO ST. THOMAS'S HOSPITAL.

THE patient was a single woman, aged 25 years, under the care of Dr. David Ferrier at the National Hospital for the Paralysed and Epileptic, Queen-square. When first seen by me, in January, 1906, she had complete left facial palsy and unhealed disease of the temporal bone. She gave a decided family history of phthisis and had herself suffered from hæmoptysis. In 1903, three years before she came under my care, she met with two severe accidents in each of which she was struck on the head, and in the second of which (a motor accident) she also sustained a severe mental shock, her companion being killed. Some six weeks after the last accident a discharge of thin watery inodorous pus was noticed from the left ear, and she suffered from tinnitus. She went to a hospital, and in March, 1904 (five months after the accident), was operated upon for the first time. The discharge continued, and so in July, 1904, a second operation was done, and in November a third, but with no better result. After the third operation the patient noticed a tendency to deviate to the right in walking, and the left side of the face became completely paralysed. The discharge continued, and in February, 1905, a fourth operation was done. A week later another operation was performed, after which the patient ha[illegible], sometimes [illegible]. stant head [illegible] July, 1905, a sixth attempt to cure the bone disease by operation was made. Some improvement in general condition followed, but the discharge continued. In November, 1905, the pain in the head became worse and was associated with giddiness and vomiting. When the discharge was free the pain was better and *vice versâ*. She frequently fell without any warning and bruised herself. Her vision became misty and she experienced difficulty in reading.

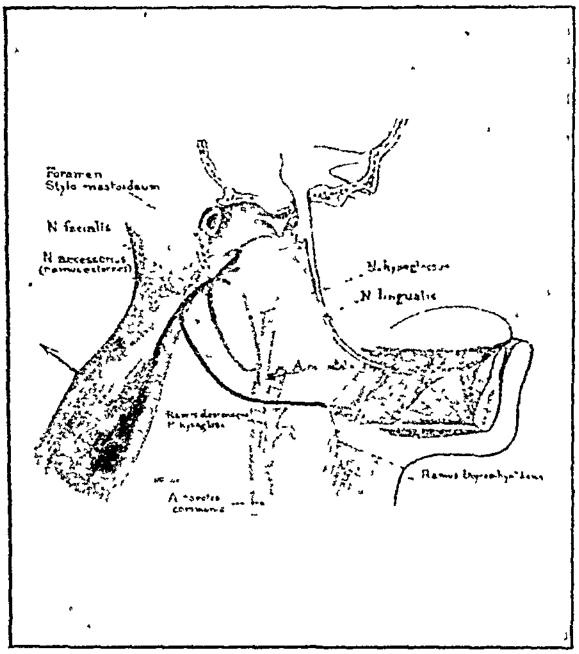
---

[1] A short account of this case was given at a meeting of the German Society of Surgery in Berlin on April 16th. At the same meeting Dr. Tilmann of Cologne demonstrated a very successful case of facio-hypoglossal anastomosis four years after operation.

When I saw the patient in January, 1906, foul pus was discharging from the left ear; the meatal flap had apparently fallen down so that the antrum could not be seen through the speculum. Pus was obviously pent up behind the flap. There was complete facial palsy on the left side; the patient suffered from pain in the left ear and from frontal and occipital headache. She was slightly ataxic on the left side. In walking she occasionally tended to deviate but the direction of deviation was not constant. There was no aerial conduction of hearing on the left side but bone conduction was still present. There was no optic neuritis, but the left external rectus was weak. The reflexes were normal. The right ear was normal.

On Jan. 24th, 1906, a radical mastoid operation was performed. I found that the facial nerve had been divided in the descending portion of the Fallopian canal, the horizontal semicircular canal had been opened, and there were two other openings into the semicircular canals as if an attempt had been made to remove them. The antrum had been incompletely exposed and was full of greenish pus. The tegmen tympani was carious and was removed; the dura over it was thickened but not perforated. In the 24 hours after the operation the patient three times passed into a curious subconscious state of low delirium, the respiration ceased, and artificial respiration and stimulants were necessary. The sight was much impaired, and the pupils were widely dilated and nearly immobile both to light and to accommodation. The sensitiveness of the left cornea was diminished. There was no diplopia. After the grafting operation was done epidermisation was soon completed.

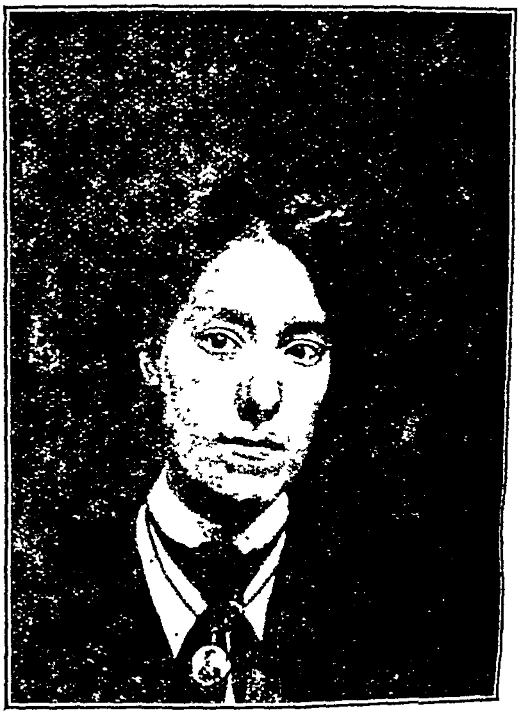
FIG. 1.



Facio-hypoglossal anastomosis. Accessory-hypoglossal anastomosis. The hypoglossal nerve was divided at the posterior border of the hyoglossus muscle. The occipital artery was then divided and the proximal end of the hypoglossal was sutured end to end to the trunk of the facial nerve which had been divided at the stylo-mastoid foramen. The spinal accessory nerve was split longitudinally and one-half was brought across the neck and sutured end to end to the distal cut end of the hypoglossal at the posterior border of the hyoglossus muscle.

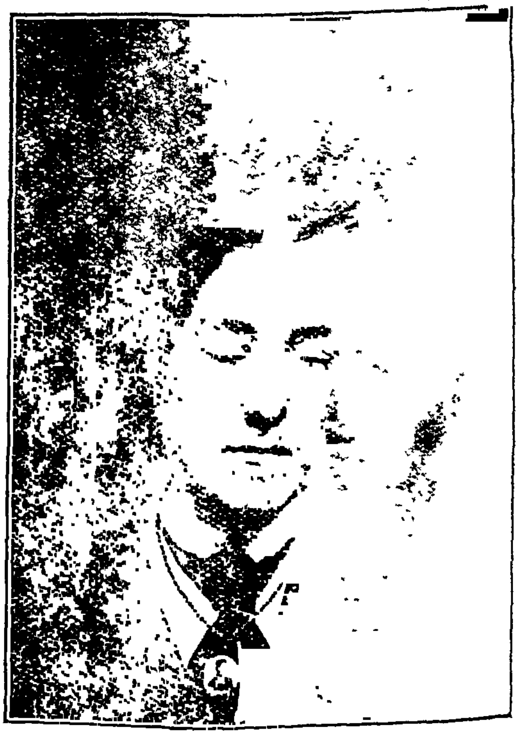
On July 4th, 1906, the patient was re-admitted to hospital. There was slight constant left internal strabismus in addition to complete left facial palsy of peripheral type. On the 10th a nerve-grafting operation was done. An incision was made along the anterior border of the sterno-mastoid; the posterior belly of the digastric was exposed and divided; the facial nerve was found at the lower part of the parotid and was identified by direct electrical stimulation; the retrahens aurem was the only muscle which responded to the stimulus. The trunk of the facial was followed up to the stylo-mastoid foramen and divided at its point of emergence. The hypoglossal nerve was found and divided at the posterior border of the hyoglossus. The occipital artery was divided between two

FIG. 2.



Facio-hypoglossal anastomosis. To show symmetry of face. The paralysis of the left external rectus occurred before the patient came under observation.

FIG. 3.

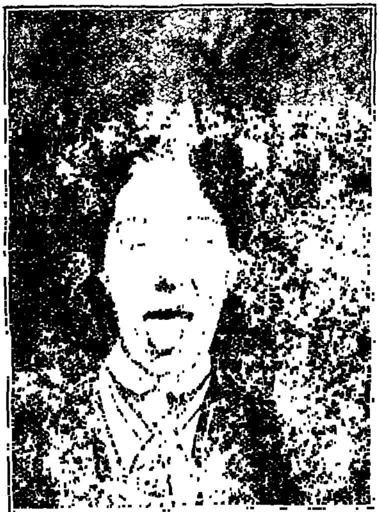


Facio hypoglossal anastomosis To show closure of eye.

[illegible] e central end of the [illegible] with the peripheral [illegible] ory nerve was next [illegible] out two inches; one-half of the nerve was divided transversely at the distal peripheral end of the slit. The strip of spinal accessory so raised up was united end to end with the peripheral end of the divided hypoglossal. The posterior belly of the digastric was sutured and the wound closed. Six weeks after the operation the left trapezius and sterno-mastoid muscles and the left side of the tongue were atrophied (*Fig.* 1).

The patient went to Canada and so was lost sight of for some time. When she returned 20 months after the operation the nutritional and functional recovery of the facial, lingual, and cervical muscles was complete. The movements of the face and tongue were dissociated, but when the shoulder was suddenly jerked a wave of muscular contraction was seen to pass from the back of the left side of the tongue towards the tip, so that the movements of the shoulder and tongue are not yet completely dissociated (Figs. 2, 3, 4, and 5).

FIG. 4.



Recovery of tongue (after atrophy from division of the hypoglossal nerve) following union with the spinal accessory nerve.

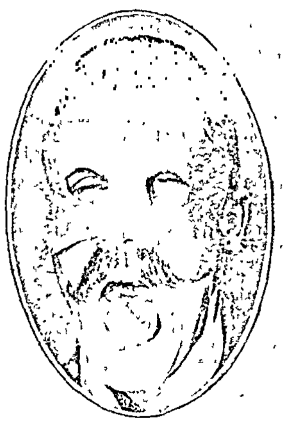
Although I happen to be the first surgeon (*British Medical Journal*, 1903) to perform a facio-accessory anastomosis (in 1895), Dr. Körte (*Deutsche Medicinische Wochenschrift*, 1903) was the first to perform a facio-hypoglossal anastomosis (in 1901), my first facio-hypoglossal anastomosis being performed in 1902. The hypoglossal nerve supplies muscles the cortical centres of which are nearer to the face centres than is the case with the cortical centres of the muscles of the shoulder. The cortical centres for the muscles of the face and tongue indeed overlap one another. It might therefore be anticipated that the prospects of dissociated [illegible] e centre for the movements of the [illegible] than when working through the [illegible] the shoulder. Moreover, it may be recalled that the movements of the tongue are closely associated with those of the lips, so much so that in health the orbicularis oris and the transverse fibres of the tongue contract together. Probably the facial nerve derives its lip fibres from the hypoglossal nucleus. There is certainly a close relation not only between the cortical face centre and tongue centre, but also between the facial and hypoglossal nuclei in the bulb. The hypoglossal nerve is therefore to be preferred for this anastomosis to the spinal accessory nerve.

Experience has shown that the atrophy of one half of the tongue leads to no material inconvenience, but that loss of power in the sterno-mastoid and trapezius muscles may be *associated with deformity, discomfort, inconvenience*, and even worse results. These are additional reasons why the hypoglossal should be preferred for the anastomosis, a view which Professor Trendelenburg endorses.

It is of the first importance to obtain in cases of facial palsy as the result of nerve anastomosis movements of the face dissociated from those of the shoulder or the tongue, as the case may be. In this way only can equal and symmetrical emotional movements, as in talking and laughing, be restored. It was shown by Professor Bernhardt[2] that in most of the cases of facial palsy which had been treated by grafting the facial nerve on the spinal accessory or the hypoglossal, although the patient did regain normal electrical reactions, associated movement of the facial muscles with those of the shoulder or tongue, and some power of voluntary movement of the facial muscles, yet the normal symmetrical play of the facial muscles in the expression of the emotions was not regained, so that the deformity, though no longer noticeable when the face was at rest, became apparent directly the patient expressed any emotional state, as in laughing or talking.

In the case I have related the movements due to emotional stimuli are symmetrical and perfect. I believe this result can be obtained only by devoting the whole nerve, either spinal accessory or hypoglossal, to the cure of the facial palsy. *Partial anastomosis such as I and others have on* many occasions done is not the right course to adopt. End-to-side anastomosis I condemn, as I do also end-to-end anastomosis with use of part only of the hypoglossal or of the spinal accessory nerve. The attempt to obtain recovery from the lingual atrophy by uniting the distal end of the divided hypoglossal to the lingual nerve on the hyoglossus muscle has in my hands failed. This case shows how a good result may be obtained without sacrificing half of the tongue or either of the cervical muscles.

FIG. 5.



Atrophy of tongue following division of the hypoglossal nerve. (After Purves Stewart.)

I am much indebted to Dr. S. A. Kinnier Wilson for the photographs of the case.

Harley-street, W.

THE SURGICAL TREATMENT OF COLITIS.[1]

By GEORGE HEATON, M.B., B.Ch. Oxon.,
F.R.C.S. Eng.,
SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM.

During the past few years certain inflammatory affections of the large intestine, which until recently had always been treated by purely medical measures, have been occasionally dealt with by surgical means, and attention has been called by surgeons to the good results which may be attained in such cases by diverting the intestinal contents from the inflamed bowel. As I have recently had under my care two cases where this has been done with happy results I have thought it might be of interest to relate them and to make some brief remarks on the present position of surgery in this connexion.

For clinical purposes the various inflammatory affections of the large intestine—excluding specific infections like dysentery and the various forms of colitis met with secondarily in such general diseases as Bright's disease, pneumonia, and pyæmia—may be divided into four main classes: (1) acute and chronic simple colitis; (2) muco-membranous colitis; (3) acute ulcerative colitis; and (4) chronic ulcerative colitis.

Of simple acute colitis I do not propose to speak. Its treatment is a purely medical one and properly comes within the domain of the physician.

Simple Chronic Colitis.

Simple chronic colitis is a disease to which a good deal of attention has been directed of late years. In its pathology it would seem to resemble the chronic hypertrophic inflammation that one sees in the nose, and it has been called "colitis hypertrophica." It is a disease of adult life and considerably commoner in women than in men. It probably owes its origin, as so many other bowel disorders do, to habitual chronic constipation. The membranous colitis, to be referred to afterwards, seems in the majority of cases to pass through this stage.

When suffering from this form of colitis the patient, who has habitually to take purgatives to get any action of the bowels, has a good deal of griping abdominal pain, and there is usually tenderness along the course of the colon. The large bowel can frequently be palpated as a thickened tender tumour in each loin. The sigmoidoscope, which should invariably be used in these cases, reveals nothing abnormal except an excessive amount of mucus coming down from the sigmoid, and this passage of mucus is a main symptom in the disease.

It is of interest from the surgical point of view in two ways. First of all, such patients are liable to mild catarrhal attacks of appendicitis by direct extension of the trouble to the appendix. In these attacks they refer all their pain and trouble to the right iliac fossa and a tender swelling may be felt there. But a similar tenderness is generally present along the whole course of the colon. In many cases there is doubtless a distension of the cavity of the appendix with mucus, and when this escapes the pain over the organ ceases. But these intermittent distensions of the appendix may be repeated indefinitely, and when so repeated undoubtedly call for surgical treatment. For at any time the distended and thinned appendix may actually burst. But when such an operation is being advised it should be made clear to the patient that the operation is being undertaken to remove the risk of a burst of the appendix and that the symptoms which are due to the colitis may still remain.

In the second place I am firmly convinced that in some cases of chronic colitis, when the symptoms have remained unabated in spite of years of patient medical treatment, a removal of the appendix will sometimes completely cure the patient, and this even when after removal there is apparently little or nothing pathological in the removed organ. I have on eight or nine occasions removed the appendix in such cases at the request of my medical colleague, Dr. T. Stacey Wilson, and in the large majority of the cases the operation has resulted in the cure of the colitis. I can only suggest as an explanation of these results that the appendix may in some cases of chronic colitis act as a storage-ground for intestinal toxins, or its contents as the culture medium of the organisms which keep up the chronic inflammatory process.

Muco-membranous Colitis.

Membranous or muco-membranous colitis is an affection about which much has been written and about the pathology of which we are still very much in the dark. Various theories are held on the subject. Nothnagel, on the one hand, regards it as due to a "perverted innervation" of the intestine and is supported in this view by the fact that it may exist without any structural alteration or evidence of inflammation being observed in the colon. Von Noorden holds that constipation is invariably the exciting cause; while Glénard and others hold that a general enteroptosis is always present and is the main factor in its causation. We know at any rate that in a certain number of cases it is associated with diseases of the female pelvic organs and that certain other organic diseases of the bowel, such as appendicitis and carcinoma, are not infrequently found in conjunction with it. It is in all probability primarily a local disorder of the large bowel in the causation of which constipation takes a large part.

Its clinical characters are fairly typical. The majority of the patients are women somewhere between the ages of 20 and 40 years. They are usually thin, anæmic, with disordered digestions and poor circulation. Neurasthenia or hypochondriasis is often present, and the complaint is commonest amongst the so-called leisured classes. There is almost invariably a history of long-continued habitual constipation. The pain is usually of a griping character and in the course of the colon. The characteristic membranous casts are from time to time passed per anum and with these casts bright red blood is frequently seen. The sigmoidoscope reveals no ulceration of the bowel and the mucous membrane in a large number of cases is apparently normal.

Such patients have as a rule weak, flaccid abdominal walls, which give a poor support to the abdominal viscera; and in consequence these viscera, and particularly the kidneys, become loose, and there is a general visceroptosis. This visceroptosis is so common as strongly to suggest a relation between the conditions. I have on one occasion performed a nephropexy on a lady with the object of ameliorating or curing the disease. The operation was successful for three or four months, but then the membranes were passed as frequently as before.

The disease is, unfortunately, a most rebellious one to treatment. Though rarely, if ever, fatal, the patients are apt to drift into a hopeless invalidism. General hygienic measures, a careful dieting, plenty of outdoor exercise, and a change of air and scene are the chief agents in improving their condition. Medicinally the main thing is to overcome the constipation, and it would seem that the best results are gained by administering castor oil in frequent and small doses. The various intestinal antiseptics—bismuth, salol, β naphthol, cyllin, and the like—are extolled by some, but they fail as often as they succeed. If aperients fail the large intestine should be washed out daily with copious enemata and this requires to be done for several months.

Of late years surgical measures have been tried and in some cases with marked success. Weir of New York was the first surgeon to do a cæcostomy, though in his case the patient had an ulcerative colitis. Since then cæcostomy, and more recently appendicostomy, has been performed a number of times by various surgeons, and a considerable number of cures have been reported. By means of these operations the large intestine is put at rest, and with a cæcostomy the fæces are entirely diverted from the disordered bowel. At the same time, through the opening thus made the colon can be daily irrigated with mild antiseptics or astringents.

For membranous colitis appendicostomy would seem the better operation, and I have lately had a most successful case, the notes of which I briefly give.

Case 1. *Appendicostomy for membranous colitis.*—The patient was a woman, aged 35 years. She had been married 10 years but had no children. As a girl she had always been troubled with constipation and her bowels had been very irregular as long as she could remember. Occasionally, after several days' obstinate constipation, she would suffer from a most troublesome diarrhœa and would pass a considerable amount of mucus.

---

[1] A paper read before the Midland Medical Society on March 24th, 1909.

For the last five years she had noticed membranous casts in the stools. These were nearly always present and occasionally she passed some bright red blood in the motions. She [illegible] ds of rest on her back in bed [illegible] had at one time or other all t[illegible] tried on her. She was a thin, spare woman with lax abdominal walls. The pain was referred along the course of the whole colon from cæcum to sigmoid. Both ascending and descending colon could be felt as firm tender swellings on deep palpation. She had a good deal of dysmenorrhœa, for which she had been treated for many years without much benefit. The bowels were extremely constipated, never being opened without purgatives or enemata. The motions contained a considerable quantity of membranous casts which were quite structureless on examination. There was a certain amount of general enteroptosis, and both kidneys were palpable but not unduly moveable. She was despondent. Her appetite was poor and very capricious. She seemed to have resigned herself to the life of a confirmed invalid. The thoracic organs were apparently normal. Her weight was 7 stones 10 pounds. She was at first put to bed and put upon a rigid Weir-Mitchell treatment. Every morning after an enema a long rectal tube was passed and the colon was irrigated with warm water. At the end of three weeks she had not improved. There was still the same abdominal pain and occasional passage of membranes and the depression had markedly increased.

The risks and inconveniences of an appendicostomy were explained to the patient and her friends, and the operation was performed in September, 1908. The operation itself was extremely simple. A small 2½-inch incision was made over the cæcum, and the appendix, which was 3 inches long and quite free from adhesions, was brought through the wound and fixed to the parietal peritoneum and skin by three catgut sutures in the upper angle of the wound. The rest of the wound was closed. The end of the appendix was cut off flush with the skin three days afterwards. A No. 10 soft red rubber catheter was passed into the colon through it, and to this was attached an irrigator containing plain boiled water. Three pints were allowed to pass gently into the bowel while a large rectal tube was in the rectum. The fluid then began to flow from the rectal tube. This lavage of the colon was repeated daily for several weeks. There was at no time any leakage from the opening in the appendix, and the only trouble experienced was an occasional difficulty in the passage of the catheter through the opening in the skin.

At the end of ten days the patient had much improved in her general condition. She lost all her abdominal pain. The sleeplessness, from which she had suffered, entirely disappeared, and she began to put on weight. Various mild antiseptic solutions were used to irrigate the colon. But none seemed any better than plain warm water. Membranes were still occasionally passed with the motions per rectum, but in much smaller masses. The irrigation was continued and is still being continued three times a week. The patient has been taught to do this for herself with the aid of a domestic servant. She expresses herself as quite well. But at present I have not countenanced the closing of the opening lest her symptoms and old troubles should recur.

Appendicostomy is to be preferred to cæcostomy for the following reasons: 1. It is a much easier operation, the shock and risks of the operation being practically *nil*. 2. It is free from the great disadvantage of cæcostomy—namely, the leakage of irritating intestinal contents through the artificial opening. 3. The opening in the appendix can be kept patent almost indefinitely, and does not confine the patient to bed, or render him an invalid. 4. The opening is extremely easy to close. In fact, it will often close itself spontaneously if a catheter is not passed through it regularly.

Acute Ulcerative Colitis.

Of the causes of acute ulcerative colitis we know but little. Some authorities, notably Rolleston, include all such cases [illegible] that bacteriological [illegible] But Osler, Allchin, [illegible]nd distinct diseases. Bright's disease would certainly seem to be a predisposing factor and the disease seems equally common in men and women.

Below are the brief clinical notes of a case lately under my care in the General Hospital and where a cæcostomy performed upon the patient when he was almost moribund undoubtedly saved his life.

CASE 2. *Acute ulcerative colitis; cæcostomy; cure.*—A collier, aged 40 years, was admitted at the beginning of September, 1907, under my colleague, Dr. T. S. Short, with headache, vomiting, and diarrhœa. He was a patient under the care of Mr. J. Bernard Garman and had been seriously ill for a fortnight. Five years previously he had had pneumonia. He had never been out of England and had always worked down a mine. On admission he was in a semi-conscious condition. His temperature was 103° F. and the pulse was 90. Sordes were present on the teeth and the breath was extremely foul, and he had profuse diarrhœa. The abdomen was distended. The spleen could not be felt. There were no rose-coloured spots. There were no adventitious sounds in his chest. An examination of his blood showed the leucocytes to number 7000 per cubic millimetre. Widal's test gave a negative reaction.

During September the patient remained in much the same state, the temperature varying from 100° to 103° and his pulse from 80 to 90, and the diarrhœa being continuous. Several times he had hæmorrhage from the bowel, having severe hæmorrhages on Sept. 28th and Oct. 7th and 11th. During October his condition became gradually worse. The diarrhœa persisted, the number of actions of the bowels increasing from 7 or 8 to 10, 12, 14, and 16 times a day. The motions were extremely offensive and often seemed to consist of pus only. His weakness and emaciation daily increased. The abdominal distension gave place to extreme retraction, bed-sores appeared on his legs and back, and though his temperature became normal or subnormal his pulse increased in frequency till it ranged from 120 to 130. Widal's test always gave a negative result. But a gradual leucocytosis made its appearance and on Nov. 4th was 20,000.

I saw the patient on Nov. 10th in consultation with Dr. Short. We decided that he had acute ulceration of his large intestine, the nature of which was uncertain, and as every kind of drug administered by t[illegible] patient was evidently going to c[illegible] checked, we decided to give [illegible] cæcostomy afforded. This was advised in order if possible to divert the fæces from the lower bowel and to enable us to irrigate the inflamed and ulcerated colon.

On Nov. 11th, two and a half months after the commencement of his illness, I performed a cæcostomy. On opening the abdomen the small intestine was thin, pale, and almost empty, and showed no signs of inflammation. The cæcum and ascending colon as far as it could be seen were thickened and sacculated in a most marked manner. His extremely weak condition would not permit of a thorough examination of [illegible] cæ[illegible] wa[illegible] a Paul's tube was tied in. Drainage, however, through this was inefficient, and it was not until the tube came away that a free drainage of the bowel was effected. After this the large intestine was irrigated daily with large quantities of warm boric lotion. Ten days later the lotion was changed for a weak nitrate of silver lotion, and this soon began to check the diarrhœa. At the same time the motions passed per rectum became more fæcal in character and lost their extremely offensive odour. The patient himself at once began to improve and put on a little flesh. He was sent home at the end of December, when the same treatment was continued daily until February, 1908, when he returned to the General Hospital and the cæcal fistula was closed for me by Mr. Frank Barnes.

The man has since then completely regained his former health. He now weighs 11 stones 5 pounds and works at his old work in the pit and keeps a small beer-house. The scar at the seat of the operation is a weak one, but gives him no inconvenience as long as he wears a belt.

Mr. Garman, writing to me on March 7th, says the patient is in perfect health and that he never remembers to have [illegible] He regards the case as one of [illegible] tion persisted in the colon [illegible] This may be so, but the

101·5° to 99° F., the patient felt better, the pain over the kidney lessened, and micturition was less frequent and less painful. In 12 hours' time, as I understood that the anti-coli serum was efficacious per rectum, and in deference to the patient's wishes, 25 cubic centimetres were given as an enema with no result. Consequently on the following afternoon the second dose of 25 cubic centimetres was given subcutaneously. The temperature within 12 hours fell to normal and the pain over the kidney and the scalding were much relieved. During the next three days the patient's temperature rose slightly, but she was obstinately constipated, and when this was relieved the temperature declined. The frequency of micturition had by this time fallen to about nine times in the 24 hours and this gradually lessened until the normal was reached.

Twelve days after the onset of the acute illness the mixed vaccine was given and caused a rise of 0·8° within 12 hours and lasting about 12 hours. Examination of the urine at this time showed only a few pus cells, and during the next fortnight these disappeared. The next injection was given in a fortnight's time and then at intervals of one month. On each occasion, however, though new needles and strict antiseptic precautions were taken, a great deal of pain at the site of the puncture was caused; there was considerable swelling, and there can still be felt a hardening of the subcutaneous tissue.

The prompt action of the anticoli serum, the absence of action of the polyvalent antistreptococcus serum, and the uselessness of rectal injection of the anticoli serum seem the points of interest in this case.

Chiswick, W.

AN INSTRUCTIVE FATAL CASE OF APPENDICITIS WITH ADVOCACY OF EARLY OPERATION.

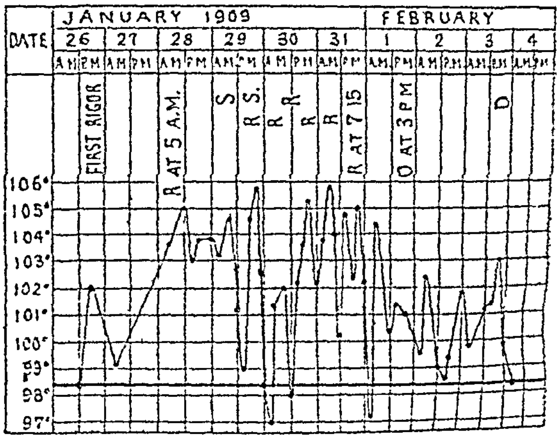
BY J. S. BODEN, M.B., B.S. LOND.,
PHYSICIAN TO THE FINCHLEY DISPENSARY,

AND

EDRED M. CORNER, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET; AND SURGEON TO ST. THOMAS'S HOSPITAL IN CHARGE OF OUT-PATIENTS, ETC.

Dr. F. J. Smith's report of an obscure and fatal case of appendicitis decided us to bring this case forward.[1] Like his, it was mysterious and indecipherable, the patient dying from pyæmia after a few days' illness. In his case general peritonitis was a part of the pyæmia. Both began with indefinite abdominal symptoms and diarrhœa. Both had rigors, which denoted the generalising of the poison, and, we know now, the futility of operation. There can only be one method of treatment likely to be successful in such cases—namely, early operation. It is to urge this and to aid others, when they meet similar obscure cases, that we venture to publish this paper.

The patient, aged 15 years, a lad of markedly bilious temperament, had not been very well for some days—"lackadaisical"—to use his mother's expression. On the evening of Jan. 21st he went to a whist drive and partook during the evening of sardine sandwiches, a sausage roll, trifle, jelly, and claret cup. Next day he was very lethargic, went to lie down on his bed in the afternoon, getting up for a walk before tea. During the evening he complained of headache, sore throat, and his temperature was found to be 102° F. On the 23rd he remained in bed all day, his temperature falling from 101° in the morning to normal by the evening; during the day he had four loose actions of the bowels. On the 24th, with the exception of a continuance of the diarrhœa (three actions) he appeared quite well, taking his ordinary food at meal times. His morning temperature being normal, he remained up from after breakfast till 10 P.M., when he went to bed apparently neither over-tired nor feverish. The first phase of the illness terminated at this time, as is shown on the chart. On the 25th he got up to breakfast and appeared well till mid-day, when he was given some bovril, which he vomited about two hours later, followed by some retching and pain in the upper part of the abdomen. He was seen that evening and found with a temperature of 98°, a pulse-rate of 82, a furred tongue, heavy breath, and some epigastric tenderness. His bowels acted twice loosely on this day. On the morning of the 26th he expressed himself as feeling better; there had been no further sickness and he said that the pain in his stomach had gone. He was thirsty, but had no desire for food. His temperature was normal; his tongue was covered with a thick white fur; the epigastric tenderness had gone, but on examining his lower abdomen there were distinct rigidity of the right rectus and an indistinct resistance to be felt just above and internal to the right anterior superior iliac spine. Just above the crest of the ilium and at the outer border of the quadratus lumborum pressure elicited pain. Per rectum there was no fulness or resistance. A provisional diagnosis of catarrhal appendicitis was made. At 6 P.M. the same day he had had a *slight* rigor and his temperature rose to 102°, his pulse-rate was 100, the "on guardedness" of the right rectus had disappeared, and a fairly definite resistance in the right lumbar region could be felt, which was not markedly tender on pressure. The bowels were inactive during the 26th and 27th. On the 27th the patient passed a very fair night, rousing at intervals of two hours for a drink, not complaining of pain in the abdomen, and able to lie quite comfortably with the right thigh extended. At 8 A.M. his temperature was 99·2°. When seen at midday it was 105°, with a pulse of 114; local examination showed no change from the previous night. At 8 P.M. his temperature was 104·6°, his pulse was 120, and his appearance strongly suggested typhoid fever. During the evening, on and off, he had pain in the right side of the abdomen, which was relieved by the application of a hot-water bottle, and passed a very fair night till 5 A.M. on the 28th, when he had a second slight rigor with a return of pain in the right side of the abdomen. His temperature after the rigor was 103·2°. At 8 A.M. it had fallen to 99·4°, but had risen again at 10 A.M. to 105° with a pulse of 105. A blood specimen was taken which gave a negative typhoid reaction. In view of the second rigor, Mr. W. H. Battle was asked to see the case and be prepared to operate. When he saw the boy at 2 P.M. the temperature was 103° and he had a good quality pulse of 98; his tongue was certainly cleaner, and it was considered that operation was not necessary on account of the lad's excellent general condition, the fact that the bowels had acted without pain twice in the night, the indefinite character of the local symptoms, the probability that the appendix was lying behind and to the outer side of the cæcum (the most favourable position for any active mischief remaining localised), and that it was the seventh day of the illness. The same evening (the 28th) the spleen could just be felt and the lad's condition was so like that of typhoid fever that relief was felt no operation had been done during the afternoon. His temperature remained fairly steadily at from 103° to 104° till next morning (the 29th), with a pulse of from *98 to 104*. At 10 A.M. his temperature had fallen to 99° and his pulse to 76. During the three days (28th to 30th) the bowels continued to act loosely from three to five times in the 24 hours. A third



R, Rigor. S, Sponged. O, Operation. D, Dressed under an anæsthetic.

---

[1] THE LANCET, Feb. 13th, 1909, p. 463.

rigor occurred on the afternoon of the 29th, his temperature at 6 P.M. rising to 105·6° (the pulse was 112), reduced by sponging to 102·6° and falling to normal at 10 P.M. and to 97° at 2 A.M. (a fall of 8·6° in eight hours). Apart from the remittent (and intermittent) temperature the boy's condition appeared good and there was no marked change either generally or locally. Dr. T. W. Hicks of Finchley saw the case in consultation on the 30th. There were no indications for operative interference and nothing could be found to account for the rigors; he had had a fourth in the early morning of that day. The local condition at this time prompted the somewhat old-fashioned diagnosis of "typhlitis," a definite, only slightly tender, sausage-shaped swelling being felt with its large axis vertical rather external to the region of the cæcum. The temperature kept very remittent on the 30th and 31st, and six rigors occurred during the 48 hours. When seen by Mr. Corner on Feb. 1st the patient was bright and cheerful, the tongue was covered with white fur, the temperature was 99·6°, and the pulse 84. The abdomen was not distended, moved on respiration, could be palpated all over, and was only tender in the right loin. The right rectus was a little more tense in its middle than the left. Some cutaneous hyperæsthesia was present in the loin and at the side; there was none in front. The liver was not tender or enlarged. Considering the *pros* and *cons* of the case the appendix seemed most likely to be the cause of the trouble, and, in view of the boy's getting worse since he was seen on the Thursday before by Mr. Battle, operation was recommended, on the distinct understanding that the infection might have become too generalised for the operation to save the boy.

Mr. W. S. Rooke, anæsthetist to the Great Northern Hospital, gave the anæsthetic. The abdomen was opened through the right rectus and the cæcum found. It was fastened by adhesions into the loin. Gauze plugs were used to pack off the peritoneal cavity, which was uninflamed, and the proximal portion of the appendix was followed to the tip which was found in a small abscess cavity under the liver at the back of the abdomen and on the outer side of the ascending colon. It was removed, a gauze plug packed in the abscess cavity, and the wound closed round the gauze drain. The boy bore the operation well. On examination the distal half inch of the appendix contained a fæcal concretion, was gangrenous at the tip, and perforated over the concretion. The patient rallied well from the operation and his condition on Feb. 2nd was distinctly hopeful; there were no further rigors, no sickness, and the bowels acted naturally twice during the day; he had an attack of faintness during the early morning of Feb. 3rd and slight icterus was noticed. He was dressed under an anæsthetic at midday, and at 2 P.M. his temperature rose to 103° and his pulse to 140 (at no time during his illness up to this time had his pulse exceeded 120), and on examination an area of harsh pleural friction was found over the lower left axillary region, with physical signs pointing to some underlying pneumonic consolidation From this time he went rapidly downhill with dilatation and failure of heart, and died at 9 A.M. on Feb. 4th.

This case illustrates many clinical object-lessons in an important and common disease. 1. The great value of early operation (within 36 hours of the onset, which would have been the only chance of saving the patient). Early operation is the method of the future; far more appendices will be removed in the acute stage and far fewer in the quiet interval. When the patient is a young subject, in whom appendicitis is so common, an exploratory operation is justifiable in the early stage, even when the diagnosis is indefinite. 2. The illness began with indefinite abdominal symptoms and diarrhœa, unaccompanied by sickness. The [illegible] that symptom is present [illegible] that appendicitis is of a [illegible] 3. Rigors are infrequent [illegible] beginning of the illness may mark the onset of an unusually toxic appendicitis. But should it occur later in the disease, a rigor suggests pylephlebitis, portal pyæmia, or general pyæmia, under which circumstances a fatal result may be expected. 4. The type of fever as shown in the accompanying chart is very unusual in appendicitis. It is markedly remittent. 5. But one of the most remarkable clinical features of the case was that when the temperature was low, the pulse was quiet, and the boy not ill; yet he was probably doomed by the time of the second or third rigor. 6. Clinically, the illness was in two phases, the first without rigors subsiding before the second began. Although the illness appeared to subside, the cause of it did not, the suppurative process reawakening and rapidly killing the patient. The almost universal formation of pus in appendicitis [illegible] fever, and rigors. It shows how both the local and general clinical conditions may be unreliable. And that in indefinite cases it is better to rely on probability—a young person with serious abdominal mischief very probably has appendicitis, the seriousness of the illness may show itself in the pulse, the temperature, the sickness, the diarrhœa, &c.—and act on that, than to rely on the very indefiniteness of the case and pursue ordinary domestic treatment.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF RUPTURE OF THE HEART.

By WILLIAM H. DAVIS, M.D. R.U.I.,
LATE HOUSE SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST; HONORARY PHYSICIAN TO OSSULSTON CONVALESCENT HOME, HENDON, N.W.

AS rupture of the heart is a lesion of somewhat rare occurrence, the following case may be of interest.

At 5.45 A.M. on July 18th, 1908, I was called to see a woman, and on arrival found her dead in bed. I had not previously attended her. She was a flabby, obese, and thickset woman, aged 62 years; her weight was 13 stones, and she was 5 feet in height. Her previous history, which I obtained from her daughter, was as follows. She had had 12 children and five miscarriages. For a considerable number of years she had been in poor health, and several attacks of influenza were the only definite illnesses recorded. For the past three years she had suffered much from œdema of the feet (worse in the evening and after standing), dyspnœa on exertion, and attacks characterised by a feeling of faintness, clammy sweats, and vomiting. Two years ago she was told by a homœopathist that she had "diabetes." The daughter stated that her mother used to drink "quarts and quarts of water and cold tea" daily, and that she was troubled by extreme irritability of the skin and "could almost scratch her legs off."

On July 16th, two days before her death, the woman attended as usual to her household duties. On the morning of the next day she complained of feeling unwell, and about mid-day had one of her "fainting" attacks, in which she lay helpless, cold and clammy, and short of breath. During the day she vomited several times and had diarrhœa and some pain in her abdomen. Her daughter first saw the vomit towards evening and she described it to me as being "chocolate-coloured." At 8 P.M., after another attack of sickness and diarrhœa, the patient retired to bed, and at 11 P.M. she had another severe attack of vomiting, on both of these occasions the vomit being as described above. At 5 A.M. the vomiting returned with increased severity, and while "straining to get anything up" she suddenly gave a rattle in her throat and fell back dead.

A post-mortem examination was held. With the exception of some passive congestion of the liver and kidneys and a dilated stomach—the mucous membrane on the anterior wall of which showed three areas of ecchymosis varying in size from that of half-a-crown to that of a shilling—the chief interest of this necropsy lay in the cardiac condition. On puncturing the pericardium about three ounces of blood-stained fluid escaped. On enlarging this opening so as to expose the heart, this organ was seen to be flabby, toneless, and collapsed, brownish-red in colour, and to be lying on a large blood clot of the size of a saucer, and about one and a half inches in thickness at its thickest part. On the upper part of the anterior wall of the left ventricle, near the septum, a tri-radiate rent was seen. When pressure was made on the ventricle blood oozed out through this opening, which was large enough to admit the tip of the little finger. On incising the left ventricle the anterior wall was found to be abnormally thin, being in fact only a quarter of an inch in thickness, and of this fully two-thirds of the outer part showed advanced fatty degeneration. The valve segments were normal, but there was some relative incompetence of the mitral and tricuspid valves.

Church End, Finchley, N.

A NOTE ON A CASE OF HYDATID CYST OF THE UTERUS; HYSTERECTOMY; DEATH AFTER 49 HOURS.

By Somerton Clark, F.R.C.S. Edin.,

SURGEON TO THE MISSION HOSPITAL, DERA ISMAIL KHAN, INDIA.

Lāl Bībī, an Afghan, from 30 to 35 years of age, was brought to hospital on Dec. 25th, 1908, by her father who is a shepherd. The patient had noticed a swelling in the suprapubic region 13 years ago. For four years this had gradually increased in size till it was of the size of a nine months pregnancy. The growth had never been painful. The appetite had always been good and the general health unimpaired. The menses had been quite regular both as to time and quantity, except for one whole year two years ago when they stopped altogether. Last year they again became regular. There had been no pregnancies.

On inspection the abdomen appeared to be fuller on the left side. On tapping two or three drops of whitish-yellow fluid escaped. Per vaginam, the cervix uteri was found to be effaced and the os uteri to be of the size of a pea, while the uterus was equally distended below and in every particular presented the condition of a woman in labour at full time.

Abdominal section was performed on Dec. 31st. The incision was three inches in length below the umbilicus. The uterus presented. The cavity of the uterus was opened and a liver trocar was thrust into the tumour, from which daughter cysts were seen to escape. On drawing the tumour out of the abdomen, the large bowel was found to be adherent for five inches. The uterus and the greater part of the tumour were then removed. The remaining part of the tumour was of the size of half a cocoanut and it could not be dissected off the bowel, and so the lining membrane was destroyed with carbolic acid and scraped. The edges were brought together with a purse-string suture. A quart of saline solution was poured into the abdomen and the wound was closed. The operation lasted for 55 minutes and at the end the patient suffered from shock. The temperature was below 95° F. During the afternoon it rose to 98°. On the next day (Jan. 1st, 1909) the patient rallied, but she became weaker during the following night. On the next morning the pulse became faster and faster and improved only for an hour after the injection of five minims of strychnine at 11 A.M. At 12 noon three pints of saline solution were transfused into the left basilic vein. At 1 P.M. the patient died. There was no sign of peritonitis.

With regard to the source of the disease, the father of the patient had never been to Australia, nor had any of his relatives. But the Povindahs, to a tribe of which this woman belonged, have dealings with Australia and work on the goldfields, pointing to the introduction of the disease from Australia.

I cannot end without thanking Miss Werthmüller, Dr. A. J. Turner, and Dr. Hal Barnett for their assistance.

Dera Ismail Khan, India.

The Society of Tropical Medicine and Hygiene.—The annual general meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., on Friday, June 18th, at 5 P.M. A dinner, limited to 60 covers, will be held the same evening (June 18th), at the Trocadéro Restaurant, Piccadilly Circus, at 7.30 P.M., Professor Ronald Ross, C.B., F.R.S., being in the chair. Tickets, 7*s.* 6*d.* each (exclusive of wine and cigars), may be purchased at the restaurant, before dinner, by Fellows and others interested in tropical medicine who have obtained admission cards from the secretaries.

Medical Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A meeting of this society was held on May 26th, Dr. James Ritchie, the President, being in the chair.

Mr. C. W. Cathcart showed the following cases: 1. A case of Mistaken Diagnosis of Malignant Disease of the Abdomen in a man, aged 32 years. In 1905 he had suffered from severe pain beneath the left costal margin for a period of two weeks subsequent to an attack of influenza. The pain had then subsided and he had remained fairly well until three months before his admission to hospital, when he had a second attack of pain and later a third attack. He had lost weight considerably and on admission on Dec. 7th, 1908, he looked very ill, but no distinct gastric symptoms were present. On exploring the abdomen a large nodular mass was found in the abdomen, firmly adherent posteriorly and impossible to remove. Mr. Cathcart was so sure of the diagnosis that he did not detach a portion of the growth for microscopic examination and he made a diagnosis of malignant disease of the stomach wall. After recovery from the operation the patient was transferred to the Hospital for Incurables, where he improved rapidly. The swelling was now going down steadily and the man was regaining health. Such a case might be taken as one of the cures of cancer brought about by the employment of any of the reputed cancer cures. 2. A female patient after Double Nephropexy by Billington's method. She had suffered much from dyspeptic symptoms, as well as troubles connected with urination, and was quite unfit for her ordinary domestic duties. The right kidney was the most freely moveable, so it was first sutured, with great benefit to the patient, and later the left kidney was treated in a similar way. She had now put on much flesh and was in every way improved. The operation consisted in stripping the capsule from off the upper and posterior half of the kidney, twisting it into a cord and hooking it over the last rib, and fixing it in this position. The bare surface of the kidney became adherent to the surrounding parts, and the organ was fixed in a better position than by the usual methods. 3. A woman, aged 22 years, after operation for Idiopathic Distension of the Colon. At the operation the whole of the large intestine was seen to be distended and this extended down into the pelvis and passed directly into the rectum without there being any band or constriction. The diagnosis was made of obstruction caused by nerve spasm of the muscular fibres. An artificial anus was made in the left iliac fossa and all the severe symptoms passed off, and she had remained well since the operation two years ago.

Mr. J. W. Dowden and Mr. J. M. Graham showed a series of patients to illustrate the Results of Treatment of Fractures of the Upper Extremity by means of Slight Support by Slings instead of by Rigid Splints. Such fractures as those of the clavicle, the greater tuberosity of the humerus, the surgical neck of the humerus, the shaft of the humerus, separation of the lower epiphysis of the humerus, and fracture of the olecranon along with double Colles's fracture were all treated by slings and daily gentle massage. In periods varying from three to five weeks the patients had all regained free use of their limbs and were without any deformity. Several of them were young children, and in these a light cardboard splint was applied at night.

Professor F. M. Caird showed a man who had lost weight and suffered from Constipation, accompanied by the passage of mucus and blood. There was a nodular fixed swelling in the lower part of the abdomen towards the left side. It was diagnosed to be a carcinoma of the sigmoid flexure. On opening the abdomen the tumour was found to be fixed to the back wall of the abdomen and to have caught up certain coils of intestine and involved them in the growth These coils were divided and sutured and the tumour was dissected off. The patient was now well.

Dr. Dawson F. D. Turner showed the following cases: 1. A woman, who developed Rodent Ulcer on the Right Side of the Nose nine months ago. She had been treated with nine exposures to the x rays and one or two exposures to radium and the ulcer was healed. 2. A lad who suffered from Warts on the Hands. These were treated by radium and had disappeared by one application of 45 minutes' duration of one centigramme of pure radium bromide. It required an interval of about 14 days before the full effect of the radium was seen, and in about three weeks from the exposure the warts dropped off. 3. A woman and a child suffering from Nævus and treated by radium. In the case of the woman the nævus on the cheek had had 19 hours' exposure to one centigramme of the pure salt at different times over different areas of the nævus. In the case of the child the nævus on the lower lip had been exposed twice, each exposure occupying 20 minutes. 4. A woman, aged 50 years, who suffered from Recurrent *Scirrhus after operation in July, 1908.* The scar was in a nodular condition and was painful. Treatment by x rays and radium was commenced in January, 1909, and the nodules had now disappeared as well as the pain. She had been treated with the Edinburgh Royal Infirmary one milligramme of radium during 49 hours.

Dr. G. A. GIBSON showed the following cases. 1. A well-marked case of Adipositas Dolorosa in a woman, aged 52 years, *who suffered from breathlessness and discomfort. She* was less than 60 inches in height and more than 60 inches in girth. She weighed 23 stones on admission but presently only 21 stones. 2. A case of Anterior Poliomyelitis, possibly due to Lead Poisoning. The patient, who was a man, exhibited well-marked wrist-drop in both hands with atrophy of the thenar and hypothenar muscles as well as those of the forearm, upper arm, and shoulder girdle. Some years ago he had been exposed to the influence of lead. The disease had commenced in the muscles of the right thumb and had spread upwards and then later had affected the left thumb muscles and left hand. *This was the same mode of* onset as in [illegible] as in lead [illegible] anterior c[illegible] Disseminated Sclerosis in a young man. All the symptoms were present with the exception of the staccato voice. The sensory symptoms were mainly altered in the manner of perversions.

Mr. DAVID WALLACE showed the following cases. 1. A man, aged 30 years, who had suffered from Pancreatic Cyst. Six months before operation he had been kicked on the abdomen by a pony, and for a few days had suffered much pain in the epigastrium, with vomiting half an hour after meals For the next two or three months he had no discomfort. The pain then recurred, with the formation of a swelling to the right of the epigastrium. The tumour was of the size of a small cocoanut and was very moveable. On opening the abdomen the stomach was found pushed up and the transverse colon pushed down by the protrusion of a cyst covered with pancreatic tissue. The cyst was stitched to the edges of the abdominal wound on April 27th, and the patient was out of bed by May 17th. A small sinus was still present, but no fluid escaped, and at no time was the discharge great, nor was it composed of pancreatic fluid. 2. A female patient *after* Partial Gastrectomy She was 56 years of age and had been troubled for several months with gastric symptoms and was very anæmic. A freely moveable tumour was *easily felt; no free* hydrochloric acid was present in the gastric secretion. The tumour was attached to the posterior wall of the stomach by a base one and a half inches in diameter, and was of the nature of an adeno-carcinoma. She was now in excellent health.

Mr. GEORGE L. CHIENE showed a lad, aged 16 years, who had suffered for four months from Pain in the Abdomen with C[illegible] ti[illegible] w[illegible] performed and an exploratory incision through the abdominal wall showed that the coils of intestine were thickly studded over with white nodules The diagnosis was made of scirrhus cancer becoming colloid

---

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in Leeds on May 21st, Dr. J. W. Martin (Sheffield), the President, being in the chair.—Dr. E O. Croft (Leeds) showed the *Left* Kidney from a fatal case of Pyelitis in Pregnancy. The patient died in coma a few hours after a series of three fits. She was six months advanced in her second pregnancy. The first pregnancy occurred six years before and the labour had been followed by convulsions. The kidney was hydronephrotic and contained a large quantity of milk-like pus. The dilated and thickened ureter contained caseous material. The right kidney was normal in size, and on naked-eye section showed evidence of slight fatty degeneration; its *capsule stripped easily.*—Dr. *Croft also showed a Large Solid* Broad Ligament Tumour of unusual character. It had been enucleated from the broad ligament of a woman aged 47 years without injuring the corresponding tube and ovary. It weighed 14½ pounds and measured 10 to 12 inches in various diameters. On section it showed a central well-defined oval mass five or six inches in diameter of the consistence of a soft uterine fibroid and of a light brick-red colour. This was surrounded by a broad band of material of a myxomatous appearance. From this area a considerable amount of fluid exuded. The tumour was apparently an œdematous fibroid which had undergone central "red degeneration" and myxomatous degeneration of the peripheral portion.—Dr. Carlton Oldfield (Leeds) showed a specimen of Carcinoma of the Cervix which had been removed by Wertheim's method. The patient was only *30 years of age. She was also suffering from syphilitic rupia* and ecthyma. One enlarged lymphatic gland was found in the parametrium close to the cervix.—Mrs. F. Orford (Pontefract) showed a specimen of One-eyed Monster (Cyclocephalus).—Dr. J. B. Hellier read the notes of a case of Double Uterus and Vagina with Unilateral Hæmatocolpos. The patient, aged 16 years, had menstruated regularly and normally for two years, with a little dysmenorrhœa. For some months she had noticed a swelling at the vulva, but only at the monthly periods. Retention of urine led her to seek advice. There was a normal vaginal passage leading to a normal cervix uteri on the left side. On the right was a cystic swelling occupying the whole length of the vaginal wall and protruding from the vulva. On incising this about six ounces of dark-red inspissated menstrual fluid escaped. The right half of the uterus was also dilated, but there was no sign of a hæmatosalpinx. The vaginal septum was completely excised. The patient had menstruated normally since.—Dr. Hellier also showed a Uterus with Double Pyosalpinx. The uterine body had been amputated because both tubes and ovaries had to be removed. There was a septum extending to the os externum and completely dividing the uterus into two cavities.

Reviews and Notices of Books.

A System of Medicine, by Emi[illegible] *the United States, and the* [illegible] *OSLER, M.D. Oxon.* and [illegible] fessor of Medicine in the University of Oxford, England; Honorary Professor of Medicine in the Johns Hopkins University, Baltimore, &c.; assisted by THOMAS MCCRAE, M.D., F.R.C.P. Lond., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Vol. IV.: Diseases of the Circulatory System; Diseases of the Blood; Diseases of the Spleen, Thymus, and Lymph Glands. The Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1908. Pp. 865. Price 30*s.* single copy, 24*s.* net per set of 7 vols

THE first article in this volume deals with general considerations in cardio-vascular disease and is contributed by Dr. Charles F. Hoover of Cleveland, Ohio. The general physiology of the vascular mechanism is reviewed and the effects of disease are briefly considered. It is stated that the auricle is capable of throwing a wave of blood into the aorta, and this statement is supported by reference to some records made by Gerhardt, to the experimental work of Hurthle, and to personal observations of the writer of the article in a case of pulsus bisferiens, but we are hardly convinced by the brief evidence here given. The myogenic and neurogenic theories of the cardiac rhythmicity are carefully enunciated, and Dr. Hoover, in his discussion, appears to hold an even balance between them and admits that the problem is unsolved. On the whole, this article is somewhat rambling in character, and, though it contains some valuable information, it is as indefinite in substance as in title.

An admirable article on diseases of the pericardium by Dr. A. McPhedran of Toronto gives a full and interesting account of the various forms of pericarditis and the other morbid changes occurring in that structure. The descriptions of adherent pericardium and of tuberculous pericarditis are much more complete than those usually given in text-books on medicine, and contain some valuable practical hints as regards diagnosis. The descriptions of hæmo-pericardium and pneumo-pericardium are also worthy of notice. Diseases of the myocardium are dealt with by Dr. Robert H. Babcock of Chicago in a well-written and carefully arranged article. The various forms of acute and chronic myocardial degeneration are clearly differentiated, the etiology, pathology, and symptomatology being adequately considered. The recommendations in regard to treatment are given in some detail and are thoroughly practical. The subject of acute endocarditis is one to which Professor Osler has devoted such special attention that the article in this System contributed by him is, as might be expected, a clear and authoritative presentation of the forms and manifestations of this group of morbid processes. Professor Osler differentiates a form of endocarditis affecting patients with an old valvular lesion and characterised by chronicity and by fever, to which he applies the name of chronic septic endocarditis. Hypertrophy of the heart is exhaustively discussed by Dr. Alexander G. Gibson of Oxford. The etiology and morbid anatomy of hypertrophy are dealt with in considerable detail, and reference is made to numerous monographs and to experimental researches. A clear distinction is made between hypertrophy occurring in a normal heart and that which develops as a defence against a pathological condition. Dr. Gibson also contributes an interesting article on insufficiency and dilatation of the heart. The arrangement of the subject matter is good and the factors leading to insufficiency, both acute and chronic, are conveniently classified.

Diseases of the valves of the heart are described in an article written jointly by Professor Osler and Dr. Alexander G. Gibson, for which we have nothing but praise, since it contains admirable descriptions of the various valve lesions and their effects, and incorporates the results of recent experimental and instrumental methods applied to their elucidation. Among the interesting questions which are discussed we may mention the third heart sound and its significance, the pathological physiology of aortic regurgitation on the basis of the experimental work of Stewart, the Austen Flint and Graham Steell murmurs, and the diagnosis of combined valvular lesions. Perhaps the best part of the article is that dealing with treatment, which abounds in wise and helpful suggestions and affords within comparatively small compass a critical *résumé* of the various modes of treatment, with their indications and contra-indications.

Dr. Charles F. Hoover contributes a learned discussion of the complex subject of functional disease of the heart. His classification of the cases and his review of the various explanations given of the protean manifestations of disturbed innervation of the heart are worthy of special attention. He also discusses the pathology of angina pectoris and clearly works out its relationship to other vascular crises.

The description of congenital heart disease, contributed by Dr. Maude E. Abbott, it would be difficult to praise too highly. The history, mode of production, pathological effects, symptoms, and physical signs of the various forms are discussed in detail, copious references are appended, and useful statistics are given. The article constitutes a valuable monograph on the subject. Professor Osler's articles on Diseases of the Arteries and on Aneurysm are also both deserving of special commendation. His consideration of the causes and symptoms of arterio-sclerosis is clear and illuminating, and is charmingly written. The description of the various forms of aneurysm is exhaustive and thoroughly up to date. His plea for method and care in physical examination on the text of the well-known dictum of Jenner's that "more mistakes are made by not looking than by not knowing," we should like to draw special attention to, for it is admirable. Dr. George Blumer of New Haven, Connecticut, treats of thrombosis, embolism, and phlebitis in a learned article, which affords a useful critical summary of present opinions on these conditions. The question of the occurrence of red or white infarcts is, however, not so fully or so clearly dealt with as the other aspects of the results of vascular occlusion. The diseases of the lymphatic vessels are described by Dr. Alfred S. Warthin of Ann Arbor, Michigan. The article includes descriptions of the various abnormal conditions of the thoracic duct and is worthy of note, since greater consideration is accorded to these conditions and to their diagnosis than is usual in text-books.

The second part of this volume treats of diseases of the blood and opens with an article on the General Pathology of the Blood-forming Organs and on the Main Data of Hæmatology by Dr. Richard C. Cabot of Boston, Mass., which, though short, is a very clear and useful statement of the general principles underlying the study of the blood in disease. The same author contributes the article on Pernicious and Secondary Anæmia, Chlorosis, and Leukæmia. The description of pernicious anæmia is admirable and contains an analysis of 1200 cases. Dr. Cabot states that in regard to its differentiation from secondary anæmias, his experience is that this can be effected from the blood examination in every case. His description of chlorosis, while thorough, contains less detail and the various theories as to its causation receive but scant discussion. Dr. Cabot states that this disease is rapidly diminishing in frequency in America. In regard to leukæmia, the view is strongly emphasised that the hæmapoietic system is not sharply differentiated into lymphoid and myeloid elements, but is essentially a single system, and thence is deduced the essential identity of all forms of leukæmia; for convenience of description, however, they are divided into three groups —myeloid, lymphoid, and atypical. Dr. Cabot doubts the existence of mixed forms and deprecates the manufacture of special names, such as leukanæmia, to designate certain atypical forms. Dr. Joseph H. Pratt of Harvard contributes a useful article on Purpura and Hæmophilia.

The third part is devoted to Diseases of the Spleen, Thymus, and Lymph Glands. In an article on diseases of the spleen Dr. Irving Phillips Lyon of Buffalo, New York, discusses the physiology and pathology of the spleen and describes the conditions of splenic anæmia and kala-azar. Dr. Warthin deals with diseases of the thymus and of the lymphatic glands. The features of enlargement of the thymus and its association with the conditions of thymic asthma and thymic death are exhaustively discussed.

This volume constitutes a very noteworthy addition to the list of medical works of reference and reflects great credit upon the editors and their collaborators.

Experimental Embryology. By J. W. JENKINSON, M.A., D.Sc., Lecturer in Embryology in the University of Oxford. Oxford: The Clarendon Press. London: Henry Frowde. Pp. viii.-341, with 167 figures in the text. Price 12*s*. 6*d*.

EXPERIMENTAL embryology, or, as some prefer to call it, mechanics of development, or physiology of development, is a comparatively new branch of biological science, and may be said to date from the time only a few years back when

Wilhelm Roux succeeded in producing a half-embryo from a half-blastomere. Growth and division of nucleus and of cell always accompany differentiation, but the production of a new form out of a relatively simple germ, comparatively structureless and unformed, and the gradual passage of this into a new individual which is like its parents, "that is the marvel which has excited the wonder of the observer and demands all his wit to understand and to explain."

In a short introduction to his "Review," as the author modestly terms his work, he acknowledges his indebtedness to an excellent model in the "Text-book" of Korschelt and Heider, published in 1902, and he gives both here and in a concluding chapter an interesting account of the views and speculations of Aristotle and others on the problems of development. In 1874 Professor W. His compared the various layers of the embryo of the chick to elastic plates and tubes; but Davenport recently carried the subject from the morphological side much further. The author incorporates part of the work of Davenport. His in 1874 not only sought a mechanical explanation of differentiation, but according to his principle of "germinal localisation" every spot in the blastoderm corresponds to some future organ—i.e., although the parts of the embryo cannot be said to be preformed in the germ, the materials for those parts are already there. Unequal growth produces the form of the parts, and so of the whole body. Wilhelm Roux raised this principle of His to the rank of a theory, which has been called the "Mosaik-theorie," or theory of self-differentiation.

The author proceeds to inquire what are the internal, and what the external, conditions that determine the course of development. As cell-division is the first—or almost the first—sign that a developing organism gives of its activity, he discusses what is known of those factors which determine the direction of division in general, and in particular the pattern of segmentation. There are several types of cell-division: (1) radial—e.g., that observed in sponges, echinoids; (2) spiral cleavage, as in molluscs and some worms; (3) bilateral, as in some fishes; and (4) irregular, as in turbellarians. Hertwig's experiments on the effects of compressing the eggs of frogs between plates of glass are quoted, and many others, such as those of Driesch on echinoderm eggs. It would appear that many of the patterns exhibited by eggs with a spiral cleavage are explicable by reference to the laws of surface-tension.

There is a short chapter on "Growth," after which the author comes to the external factors which affect the development of an egg, and he deals successively with the following points: 1. Gravitation. In many cases this has no effect; but there are some instances where it affects development. 2. Mechanical agitation. Pelagic ova afford instances in which this may be considered. The hen's egg requires a small amount of movement; the hen turns her eggs every day, and in artificial incubation this must be done, else, as Dareste has shown, the allantois sticks to and ruptures the yelk sac in unturned eggs. Violent agitation of a hen's egg is fatal. 3 and 4. Magnetism and light. These do not seem to exercise a directive influence generally, though certain qualities of light injuriously affect development of certain ova. 5. Heat. This, of course, is important. O. Hertwig has made a careful investigation into the conditions of temperature for the development of frogs' eggs. The normal temperature here is from 15° to 16° C., though the optimum is somewhat higher, and it is of no small importance to observe that the definitive distribution of specific substances in the unsegmented egg, and so the determination of the embryonic axes, may be brought about partly at least by the spermatozoon, from its actual point of entrance along its "penetration path."

We have said enough to show the great interest attaching to the whole problem, a problem perhaps new to many English readers. To the trained embryologist we commend, not only the material part of the work, but the keen critical dissection of the very suggestive theory of Driesch and various other theories which so largely prevail in the domain of a recent but very abstruse department of natural knowledge. Apart from the formation of "monsters" under very abnormal conditions, great interest attaches to the study of "variations," "sports," "mutations," by varying these external factors, and the problem that confronts the experimentalist is to determine the part played by each factor of the external environment.

About one half of the book is devoted to the "Internal Factors." The author begins with "The Initial Structure of the Germ as a Cause of Differentiation," and later there is a short but interesting chapter on the action of the parts of the developing organism one on another. The former is considered very elaborately, for nearly all groups of the animal kingdom are passed in review, from amphibia to cœlenterata. This is the part that is of the greatest interest to the specialist. The author gives a careful *résumé* of the conclusions and considerations to be drawn from an elaborate series of experiments, one of the most important deductions being that the cytoplasm of the undeveloped ovum is not homogeneous and "isotropic," as was suggested by E. Pflüger in 1883, but heterogeneous and "containing various specific organ-building stuffs which are definitely and necessarily connected with the production of certain parts or organs of the developing animal" (p. 240). The removal of these "stuffs" entails the absence of the corresponding organ later.

This is a thoroughly interesting book.

Injuries and Diseases of the Knee-joint considered from the Clinical Aspect. By Sir WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. Eng., Consulting Surgeon to St. George's Hospital and to the Hospital of St. John and St. Elizabeth; Senior Surgeon to the Seamen's Hospital, Greenwich. With 34 illustrations. London: James Nisbet and Co., Limited. 1909. Price 4*s.* 6*d.* net.

THE largest joint in the body is extremely liable both to disease and injury, and in both cases the importance of the condition is so great as to justify the devotion of a volume to their consideration. And we know no surgeon better qualified than Sir William Bennett to write such a book, while we are glad that he has taken for discussion the various lesions from their clinical aspect only, for by doing so he has increased the practical value of the work materially by giving it a well-defined scope.

A short description is given of the normal knee, and the importance of the ilio-tibial band is pointed out; two skiagrams, showing the joint in extension and flexion, demonstrate clearly how little protection the patella affords against wounds from the front, for in all positions of the joint a considerable area of the synovial membrane is vulnerable both above and below the patella. In the treatment of acute effusion into the joint, whether hæmorrhagic or serous, the author is opposed to the application of ice, and he quotes a case in which the application of an ice-bag to an injured knee was followed by sloughing of the skin over the patella. Ice relieves somewhat the pain in effusion, but he has come to the conclusion that hot compresses are preferred by most patients, and the local effect is better. He points out that the mere tension of an acute effusion may send the temperature up to 103° F. For this acute pain he advises gentle shampooing with a very light hand; he has found that patients, restless and irritable from pain, can be sent to sleep sometimes in a few minutes in this way. He is opposed to complete immobility in these cases of acute effusion, and as soon as the tension begins to lessen he advises gentle movement of the joint by the patient. This gentle movement, he considers, favours absorption and prevents adhesions.

An important chapter is that on painless effusion into the knee-joint. It is by no means a rare condition, but very little about it has appeared in print. Sir William Bennett has seen it mainly in women and girls, and in most cases there has been marked menstrual or uterine trouble, and often anæmia. A slight injury to one knee may draw attention to marked effusion, but on examination it will be found that the other knee also contains fluid. The re-establishment of menstruation or the correction of the abnormality is in many of the cases followed by disappearance of the fluid. The condition may occur in boys, and Sir William Bennett thinks that here it is generally associated with phimosis or some other affection of the external genital organs, when if this be remedied recovery follows. We have not met with any such suggestion previously, but it is of great interest and importance, and it should not be difficult to obtain evidence on the point. The medical officers of schools would be in the best position to test the accuracy of the existence of such an association.

The chapters dealing with what has been called "internal derangement of the knee-joint" are of much interest. As to its frequency the author has found damage to the semilunar cartilages in nearly two-thirds of all cases of affection of the knee consequent on injury. The left knee was more than twice as frequently affected as the right. The injury done to the cartilage may vary greatly. In some cases it is merely bruised, but the consequent swelling is sufficient to prevent complete extension of the joint. Absorption may remove the blood and serum effused into the cartilage, but sometimes it is necessary to remove the swollen cartilage, as in one case detailed in the book. In other cases where a displaced cartilage has not been returned to its rightful position it tends to become sodden and felt-like, and this condition is doubtless favoured by the constant grinding pressure to which it has been subjected during movements of the joint; inflammatory processes are set up and it becomes difficult to recognise the tissue as the fibro-cartilage. Sir William Bennett points out that in recurrent displacement the following points will generally be noticed: 1. The tendency to recurrence is in direct proportion to the looseness of the knee-joint and the wasting of the muscles of the thigh. 2. With repeated attacks the effusion gradually tends, in most cases at least, to diminish in quantity with each attack until it may no longer be seen. 3. The severity of the injury necessary to produce the symptoms diminishes with successive attacks. 4. In a certain proportion of cases the occasional recurrence of effusion with a feeling of weakness is the only symptom. 5. In course of time in some cases the attacks, though frequent, may cause so little inconvenience, and the displaced cartilage is so readily reduced, that little or no disability arises. 6. If the displacement of the semilunar cartilage is into the intercondylar notch all symptoms of abnormality may disappear.

The treatment advised by the author is this: The displaced cartilage must be reduced as soon as possible, and the joint is then to be kept at rest until the effusion has gone, massage of the muscles and the knee being very useful in assisting the absorption of the fluid. This early massage also checks the rapid muscle waste. The disappearance of the effusion rarely takes more than a week and then movements may be begun, but rotation must be avoided. The massage must be continued for a period of from three weeks to six months. So long as the thigh muscles are wasted or the capsule is loose, massage must be continued. When treatment fails operation is indicated, but Sir William Bennett thinks that if the early treatment is correctly carried out operation is needed in only a small proportion of cases. The cases in which operation is clearly indicated are, firstly, those in which non-operative measures have conclusively failed; secondly, those in which general flaccidity of the joint, as shown by an abnormal amount of lateral movement upon manipulation, is in excess of the other symptoms; and, thirdly, those in which a speedy cure is urgently called for by special circumstances. The incision preferred by the author is longitudinal, commencing above about half an inch from the edge of the patella at its centre and extending downwards to a little beyond the line of the articulation, and he maintains that this incision gives ample room for every purpose. He lays great stress on the importance of never operating while there is fluid in the joint.

We have examined particularly this section of the work, as it is one which is of special interest at the present time, for more attention is now being paid to abnormalities of the fibro-cartilages of the knee than hitherto, as it is being recognised that many obscure pains in the knee are associated with slight injuries of the cartilages. In the remaining chapters of the volume, we may say that we have been impressed by the evidence of Sir William Bennett's intimate acquaintance with his subject, so that we feel sure that the book will be valuable to all who have to deal with injuries or diseases of the knee-joint, both to general practitioners and to those who are operating surgeons. The wide experience of the author supplies principles and details from which all may derive benefit. The book contains many illustrations, including a number of skiagrams which help to make its reading and comprehension easy.

Manuel de Thérapeutique Clinique des Maladies Tropicales. Par le Dr. A. GUILLON, Medecin-Major de 2e Classe des Troupes Coloniales; Professeur-adjoint à l'École d'Application du Service de Santé des Troupes Coloniales. With illustrations in the text Paris: Octave Doin et Fils. 1909. Pp. 387. Price 7 francs.

THIS work on the treatment of tropical diseases is written by a French military medical officer for practitioners on land or sea in tropical regions, more especially for those living in isolated places where books of reference are not available. It forms a very compact and practical text-book, omitting historical and bibliographical reference, but embodying very full therapeutical and other treatment; and, what is more important, it furnishes prescriptions recommended by recognised authorities on the treatment of tropical diseases, amongst whom we note the names of Sir Patrick Manson and several officers of the Royal Army Medical Corps and Indian Medical Service. The first chapter covers Asiatic cholera, yellow fever, and plague. The Roux-Yersin serum, as employed in the French colonies, is recommended for the treatment of the last-named disease In the section dealing with the treatment of dysentery the advisability of the surgical treatment of very chronic forms of the disease is well described, and the establishment of an artificial anus at the level of the cæcum is recommended to allow the large intestine to obtain rest and to be washed out. Manson's treatment on the same lines is mentioned. The treatment of tropical liver abscess is also well described. Kala-azar, a disease in which considerable interest has been aroused recently, is well, though somewhat briefly, described. Its geographical distribution is laid down as covering India, China, and Tunis. Experimental treatment by atoxyl in large doses is recommended, and from the fact that the Tunisian parasite has been found in dogs the possibility of a curative serum derived from this source is suggested. The treatment of tropical skin diseases is fully described. We notice the application of balsam of Peru in the treatment of itch is regarded as an efficacious one, and a complimentary reference is made by the author to the officers of the Royal Army Medical Corps who introduced this specific treatment. The treatment of the two forms of bilharzia disease, intestinal and urinary, deserves mention, as well as the sections dealing with bites of snakes, scorpions, and poisonous insects Ptomaine poisoning from eating poisonous meats, fish, and vegetables is very fully described and suitable lines of treatment laid down. Beri-beri, elephantiasis, sunstroke, heat-stroke, and other pathological conditions met in the tropics, are embodied in the concluding chapters.

The book can be recommended confidently to medical men practising in the tropics.

LIBRARY TABLE.

Suture of Arteries, an Experimental Research. By E. ARCHIBALD SMITH, M.B., Ch.B. Vict., F.R.C.S. Eng London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 70. Price 2s. 6d.—The suture of arteries is assuming an important position in surgery, for on its performance depends the practicability of some of the most recent suggestions in plastic surgery, such as the transplantation of organs. Even in mere wounds of vessels it is not without great value, for to be able to suture a wounded artery would greatly diminish the risk of gangrene of a limb. It is not without interest to note that the first successful attempt to suture an artery was made exactly 150 years ago, for in 1759 Lambert of Newcastle devised, and Hallowell put into practice, the suture of an artery which had become the seat of a traumatic aneurysm. The idea was revived by Gluck in 1881 and many experiments have been made since, with more or less success. The cases in which arterial suture has been performed in man are few; in 1903 Jensen was able to collect eight cases, and Mr. E. A. Smith has added 12 others. This little book contains an account of a number of experiments on animals performed in Vienna with the view of discovering the most suitable form of arterial suture. Mr. Smith goes through the methods hitherto employed, and then describes that which he himself considers to be best. This is a form of quilled suture, in which a small piece of catgut takes the place of the quill. For a longitudinal wound of a vessel this suffices, and it is also suitable for end-to-end suture, in all cases the edges of the wound being turned outwards so as to bring intima into contact with intima. For longitudinal wounds it might be thought that some narrowing of the vessel at the site of the suture might occur, but we are told that in practice this is barely noticeable, and Mr. Smith thinks that the narrowing is not permanent. For the more easy practice of this method of suture he has devised several ingenious instruments. The special merit of this form of quill suture is that it shows little or no tendency to cut out. The author holds that if an artery be carefully sutured there is a *restitutio ad integrum*, for new elastic and muscle fibres form in the scar and it is lined internally by normal endothelium. A chapter on the histology of the cases is given, and the list of references to papers on the subject should prove useful to future investigators.

Aids to Medicine. By BERNARD HUDSON, M.D. Camb., M.R.C.P. Lond., Assistant Physician to the City Road Chest Hospital; Pathologist and Registrar to the East London Children's Hospital; late Casualty Physician to St. Bartholomew's Hospital. London: Baillière, Tindall, and Cox. 1909. Pp. 252. Price, cloth, 3s. net; paper, 2s. 6d. net.—The object of this little handbook is to supply the student with a book for revision purposes of a convenient size to carry in his pocket, and, as stated by the author, it is not in the least degree intended to serve as a substitute for any of the many excellent text-books on medicine. It is an admirable little "cram" book, and as such books appear to be an unavoidable feature of modern medical education, this one may be recommended, for it may well prove useful to fortify students' memories just before they are to be tested by final examinations in medicine. The type is good, there is a good index, and practically the whole of modern medicine is well and concisely covered.

A Practical Course of General Physiology for Medical Students. By D. NOEL PATON, M.D. Edin., F.R.C.P. Edin., Professor of Physiology, University of Glasgow; and G. HERBERT CLARK, M.B. Glasg., D.P.H. Edin., Muirhead Demonstrator of Physiology, University of Glasgow. Glasgow: James Maclehose and Sons 1908. Pp. 39 Price 1s. net.—In order to encourage accurate observation and correct interpretation of the results obtained by simple physiological investigation, the authors have prepared a syllabus giving directions for the performance of a series of experiments to illustrate the chief properties of living tissues without indicating the results likely to be obtained. It is directed that the experiments shall be carried out before the student attends lectures on the subjects he is working at. The book is interleaved to enable him to record his results, and the directions given are full, clear, and sufficient. The subjects to be worked at include the properties of protoplasm, muscle, nerve, reflex actions, the senses, the circulation, and respiration. The idea is a good one, and it should serve to render the course of practical physiology a more useful training than where the student strives after an expected result.

Arterio-sclerosis: Etiology, Pathology, Diagnosis, Prognosis, Prophylaxis, and Treatment. By LOUIS M. WARFIELD, A.B., M.D. With an introduction by W. S. THAYER, M.D. With eight original illustrations. St. Louis, Mo.: C. V. Mosby Medical Book Co 1908. Pp 165.—The condition of arterio-sclerosis, although in the strict sense a pathological condition of the blood-vessels, with a varied etiology and a complex symptomatology depending largely upon the distribution and degree of its incidence, is described by the author as a clinical entity. He lays stress upon the frequency of the occurrence of early arterial degeneration and its association with the conditions of hard work, worry, and high living. Without being discursive he gives a general account of the condition and of its clinical manifestations in clear and simple language. Treatment is discussed in some detail, and especial emphasis is laid upon the importance of early recognition and of the carrying-out of measures to prevent the advance of the pathological process. Dr. Warfield would like to see men and women past the age of 40 submit themselves to a routine medical examination twice a year in order to find out if they are in sound health. Such a proceeding, if generally adopted, would no doubt serve the useful purpose of drawing attention to the importance of care in regard to their mode of life in many persons who, without apparently suffering, overtax their powers, and who eventually come for treatment only when irreparable damage has been done.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In the May issue Dr. Byrom Bramwell discusses the teaching of medicine at Edinburgh and points out the existence there of the malady from which London is equally suffering—the multiplication of lectures and consequent lack of time for clinical observation. He even suggests the abolition of so-called clinical lectures, which are seldom instances of really valuable clinical teaching. Mr. A. Logan Turner writes on orbital complications of suppuration in the frontal and ethmoidal sinuses; and articles dealing with renal decapsulation as a treatment of puerperal eclampsia are contributed by Sir J. Halliday

Croom, Dr. R. C. Buist, and Dr. H. Oliphant Nicholson. Notes of cases of removal of foreign bodies, intentionally swallowed, from the alimentary canal are recorded by Mr. J. Hogarth Pringle and Mr. Alexis Thomson.

The Dublin Journal of Medical Science.—An interesting paper on atrophy of the testicle, written by Dr. Charles Greene Cumston, is published in the May number of this magazine. Mr. F. Kennedy Cahill discusses the causes of the collection of gas in the stomach and the treatment to be adopted in different forms of the disorder, and Mr. W. I. de C. Wheeler writes on local anæsthesia in minor surgery and its relation to reactionary pain. Dr. W. R. Dawson considers the Irish recommendations of the Royal Commission on the Care and Control of the Feeble-Minded.

The Birmingham Medical Review.—The existence of apparently healthy persons who yet act as "typhoid-carriers" and spread the infection of this disease has been much discussed recently, and any light that can be thrown on the question is of value. In the March issue of this journal Dr. J. Miller discusses some recent investigations on this subject and records a case of his own in which the bacilli were found, not only in the gall-bladder, but also in a necrotic area of the liver. It would appear that infection of the bile-passages is effected through the blood stream. In the same number Dr. W. A. Potts discusses the causes which lead to the birth of feeble-minded children, among which maternal intoxication, either by alcohol or infective diseases, appears to be pre-eminent.

ERRATUM.—In our review of the collected papers of Lord Lister which appeared in THE LANCET of June 5th, p. 1603, the price of the book, owing to a slip on the part of the reviewer, was given as "£2 2*s.* each volume." It should have been £2 2*s.* net the set.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, JUNE 1ST.

THE General Medical Council resumed its sittings to-day at the offices of the Council, 299, Oxford-street, W. The President, Sir DONALD MACALISTER, occupied the chair.

Dental Surgery Licences.

The Dental Education and Examination Committee submitted the following report:—

> A letter has been received from an educational body, the Incorporated Dental Hospital of Ireland, calling attention to a certain difference existing between the requirements of the several bodies granting licences in dental surgery. The recommendation of the General Medical Council, which is to be found in the regulations for the registration of medical and dental students, 1903, p. 18, is "One year *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study." It appears that the Royal College of Surgeons of England allows two years of such study to be counted towards the four years of the curriculum, but that the other licensing bodies only allow one year to be so counted. As from the printed regulations the actual practice of some of the bodies is not obvious, inquiries have been made by the Registrar and answer received. The regulation (2) of the Royal College of Surgeons is "of having been engaged during a period of not less than two years, in acquiring a practical familiarity with the details of mechanical dentistry under the instruction of a competent practitioner, or under the superintendence of the mechanical department of a recognised dental hospital, where the arrangements for teaching mechanical dentistry are satisfactory to the Board of Examiners in Dental Surgery."

Mr. HENRY MORRIS referred to the recommendation of the General Medical Council—namely, that "one year *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study." If only one year of professional study might be counted, then the curriculum became a five years' curriculum or else the period passed in a dental hospital had three years allotted to its final stages, which was one year longer than was required. It is allowed by those who are best acquainted with the actual practical work that two years for general and surgical subjects are sufficient, but that two years are required at least for education in mechanical dentistry. The requirements of the General Medical Council are that there should be two years at least of training in mechanical dentistry and that there should be a four years' curriculum, thus requiring that either the whole of the two years of training in mechanical dentistry must be passed in a dental hospital or else that the curriculum becomes one of five years. The Royal College of Surgeons of England are convinced that the education in mechanical dentistry which students got under a proper director in the hospital was infinitely superior to that which they got as apprentices of dental practitioners throughout the country. The aim and object of the College was by degrees to make the whole period four years, including two in mechanical dentistry to be passed under the direction of the hospital. That was the reason why in 1906 they changed the requirement of three years' practice in mechanical dentistry to two years, because they hoped if it was reduced to two years those two years would be passed in a dental hospital. And that is really the tendency at the present time. But the time has not arrived when that can be done, for the reason that there is not provided in all places where dentistry is taught in this country sufficient laboratory accommodation for the education in mechanical dentistry for all students who are training. The hope of the Royal College of Surgeons is to get the two years included within the four years' curriculum because more than two years for general work are not required.

The report was adopted.

Mr. MORRIS moved—

> That the report of the Dental Examination Committee be communicated to the Royal College of Surgeons of England with such observations as it may be desired to offer.

Sir CHARLES BALL seconded.

The motion was agreed to.

Penal Cases.

The Council resumed consideration of a charge against Robert Galbraith Reid, registered as of 202, Ewell-road, Surbiton, M.B., Mast. Surg. 1887, Univ. Glasg., who appeared before the Council in answer to a summons.

The Council came to the conclusion that the facts alleged in the notice of inquiry had not been proved.

Report of the Education Committee.

The next business was to receive a report from the Education Committee on various proposals submitted to it referring to the curriculum in medicine. At the suggestion of Dr. NORMAN MOORE an understanding was come to to defer the discussion of the details of the report until the November session, when it would be given a foremost place in the programme of business.

Dr. MACKAY, the chairman of the Education Committee, then moved that the report should be entered in the minutes.

Mr. THOMSON moved as an amendment that the report should also be circulated to the licensing bodies for their information.

Mr. MORRIS, in seconding the amendment, remarked that it would be well if the licensing bodies considered the report before the Council came to a final decision.

Dr. MACKAY replied that if the Council were proposing a very drastic change in the Regulations and were not sure of opinion on the matter it might well go to the licensing bodies for suggestions. However, it was now proposed to add to the recommendations and not to the requirements of the Council. All the facts and figures had been before the bodies.

The amendment was rejected on a show of hands.

The motion that the report should be entered in the minutes was agreed to.

The report deals with various proposals submitted to the committee for consideration. In it it is stated that the committee does not recommend the exclusion of chemistry, physics, and biology from the curriculum of medical studies and their transfer to a preliminary stage. Further, the committee does not recommend at the present the addition of a year to the curriculum in medicine.

In a concluding portion of the report the following passage appears:—

The committee believe that a period equivalent at least in time value [illegible]

It will be seen that the proposal implies that in cases where there is no overlapping the undivided study of the Final subjects must be begun, when the minimal course is to be followed, in the middle of the third year In many of the licensing bodies the completion of the examination of the first period does not take place until this point has been reached It is however the practice among these bodies *to commence the work for the Final* Examination at the beginning of the third year In the cases referred [illegible]
course i[illegible]
overlapp[illegible]
months' [illegible]
Period

When the work for the Final Examination begins at the commence [illegible] ompletion of the [illegible] ccording to the [illegible] will necessitate [illegible] The subjoined [illegible]

Date of commencement of work for final examination	Date of completion of examination in anatomy and physiology Months	Length of period of study for final examination Months				Total length of curriculum Months
		Overlapping study	Undivided study	Total	Equivalent value of total	
Beginning of third year	*30*	6	27	33	30	57
„	36	12	21	33	27	57

Reappointment of Registrar

Mr H E ALLEN was appointed Registrar

Vote of Thanks

On the motion of Dr NORMAN MOORE a vote of thanks was awarded to the President for his services in the chair

The summer session then came to an end, the Council adjourning until November

MEDICINE AND THE LAW.

Fergusson v *the Malvern Urban District Council*

IN THE LANCET of Feb 15th, 1908, p 517, we congratulated Dr J C Fergusson upon the recovery of damages against the Malvern urban district council in respect of the pollution of water used at the hydropathic establishment conducted by him, which caused an outbreak of enteric fever among its inmates At the same time we indicated certain points upon which there had been findings of fact by the jury, and as to the legal bearing of which argument in the Court of Appeal was likely to follow The jury found that the defendants, the Malvern district council, were guilty of negligence in permitting sewage to escape from their sewer and to contaminate certain water which the plaintiff made use of for his establishment, and they also found definitely that this contamination of water by sewage was the cause of the outbreak of fever, and not, as was suggested, defects in the plaintiff's drains The first two questions put to the jury were, however, (1) Had the plaintiff any proprietary right in the water flowing from the Tudor *well to his tank ?—to which the answer was in the negative ;* and (2) Had the plaintiff any licence from the owner to use the said water ? To this also the answer "No" was returned, and it must be added that all the questions thus put were agreed between the counsel for the parties as embodying the issues of fact at stake In these circumstances it will readily be seen that the legal right to compensation claimed by Dr Fergusson was open to grave doubt The water was polluted by sewage through negligence on the part of the defendants, but they did not supply him with it *for drinking or for any other purposes, and they were not* aware that he was taking it In the terms of the questions and answers quoted he had no proprietary right in the water, and those who had such right had given him no licence to use it The Court of Appeal decided that the findings in question were fatal to the plaintiff's case and deprived him of the judgment obtained at the trial, summarising the point as to the mutual position of the parties in a decision which has now been upheld by the House of Lords In giving judgment on May 23rd the Lord Chancellor said that the real question was whether there was a lawful enjoyment of the water by the plaintiff, that the jury had negatived any such enjoyment, and that strict justice had been done by the judgment of the Court of Appeal Lord Macnaghten concurred Lord James of Hereford referred to the damage undoubtedly suffered by the plaintiff, but did not consider that he had any chance of establishing his case on a new trial Lord Shaw was equally unable to say that there should be a new trial, although he expressed some doubt as to whether the question of the lawful enjoyment of the water had been clearly put to the jury It is to be regretted that Dr Fergusson, in addition to the *grave losses already sustained* by him, should have to bear the heavy cost of unsuccessful and protracted litigation

THE CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY —In THE LANCET of May 15th (p 1427) we described briefly Einthoven's string galvanometer, which was exhibited by Professor A D Waller at the recent conversazione of the Royal Society, and in our issue next following (p 1448) we published a paper by Professor Waller describing Einthoven's recent electro cardiographic researches Physiologists and others should know that the very delicate string galvanometer which forms the chief part of Einthoven's apparatus is being made in this country by the Cambridge Scientific Instrument Company, Cambridge

THE LANCET.

LONDON: SATURDAY, JUNE 12, 1909.

National Control over the Purity of Foods.

AT the International Congress of Applied Chemistry, which concluded its multifarious activities last week, a useful series of papers on chemical and technical questions relating to the purity of food were contributed to the section which went by the hitherto unfamiliar term of "Bromatology." The section devoted two meetings to a discussion on National Methods of Food Control, and another to Food Standards. Dr. W. H. WILEY gave an interesting and characteristic address on the origin and progress of the "pure food" movement in the United States, in which he has played so prominent and distinguished a part. Dr. EUGÈNE ROUX and Dr. F. BORDAS described the important administrative organisation for the repression of fraud and falsification in articles of food, which is rapidly being developed in France under their direction as a result of the legislation of 1905; and Dr. A. MCGILL showed the progress made in the same direction in Canada by methods which are based partly on American and partly on British experience. Dr. WYSMAN and Dr. VAN RHYN expounded the system in Holland, by which trading associations and the State work together in a system of supervision over the production of unadulterated butter and other articles. Dr. G. S. BUCHANAN undertook the task of summarising British legislation and administrative methods, while the Italian, Belgian, and Swiss organisations for controlling the purity of food were also explained by representatives of these countries.

As might be expected in a discussion from the point of view of applied chemistry, attention was chiefly directed to two of the many ramifications of the question of "pure food"; viz., the protecting of the consumer against the introduction into foodstuffs of deleterious or poisonous substances, and the providing of him with security that the article which he buys corresponds within reasonable limits to the description given of it. The earlier attacks on food adulteration were naturally concentrated to a large extent on the first of these questions. It was then found that dangerous substances were being employed which could readily be detected by the analyst and which no one could be found openly to defend: red lead in pepper, Scheele's green in sweets, and many other examples could be given. In this country the Sale of Food and Drugs Act of 1875, with its machinery of sampling and public analysis, practically put an end to such practices, and we owe it to the efforts of WAKLEY, HASSALL, and other reformers of the period that England took a lead among nations in this respect. The questions which demand attention at the present time are considerably more complicated, and in dealing with them administrative and economic considerations become at least as important as the determinations of the analyst The case of preservatives is a familiar example of the complexity of the matter where the introduction into foods of potentially injurious substances is concerned. All countries are not at present prepared to adopt Dr. WILEY'S view that any preservative substance, other than traditional articles like salt and wood smoke, ought to be entirely prohibited in every food. They are disposed rather to compromises which admit certain specified preservatives in particular cases under strict regulations, while excluding them in instances where no sufficient commercial necessity for their employment can be shown, and no compensating advantage would be gained by the public if their use is permitted. The complexity of pure food "control" is even more strongly illustrated by discussions on means for preventing inferior substitutions and "imitation" articles being passed on to the public as "genuine" products. The difficulties which are met with in obtaining uniform action in this matter are well known to those who have experience of the working of the English Sale of Food and Drugs Acts. The discussion at the Congress showed that in our colonies and in foreign countries the same difficulties are being actively met by the prescription of "pure food standards" and *definitions of* genuine products, and by measures which *supplement* or supersede a system of control, based on analysis of samples sold by retail. These form a systematic check over the proceedings of the food manufacturer or importer, and so *fix* in the right quarter the *responsibility* for the description which is given to the article sold. In France this is being done for special classes of foods by a series of administrative regulations made under the recent pure food law of that country. In such cases, for example, as the sale of pure olive oil and of mixtures of olive oil and cotton-seed oil, or of Cognac brandy and mixtures of Cognac with other spirits, the regulations leave no doubt as to the *obligations of the trader* at every stage, and are enforced by a special service which has the aid not only of chemical research but also of trade experts. We are glad to note that there seemed to be a general agreement among English speakers in favour of centralised action in similar directions in the United Kingdom. It would no doubt involve an addition to the benevolent bureaucracy of Government departments of which Mr. JOHN BURNS has lately spoken with so much approval, but after all if questions such as these are required to be settled they are essentially questions for the bureaucrat, provided he obtains the best expert advice and hears all sides. The Local Government Board has lately usefully exercised its "bureaucratic" powers by supplementing the action of local authorities under the Public Health Acts by special regulations relating to imported foods, and it seems very desirable that the same kind of proceeding should be followed in connexion with local administration of the Adulteration Acts.

Many of the subjects which were reviewed at the discussion referred to had, of course, little direct medical interest. People need not be poisoned when they eat articles sold to them as chocolate which are practically innocent of any acquaintance with the cocoa bean, raspberry jam which is largely apple pulp, brandy which is three parts grain spirit, or vinegar which is mainly a solution of commercial acetic acid. The inferior article is often deficient in food value or in flavour, but the harm done to the consumer in many cases is principally that he is induced to pay more than the imitation article is worth on the strength of the reputation which the genuine article enjoys, while the maker of the latter often becomes driven by the competition of the inferior product to debasing the quality of the higher-class material. The fair position in cases of this kind seems to be that which has been elaborated in our butter and margarine legislation. Here are two products of different origin, one the "natural" and the other the "imitation," which may be practically indistinguishable to the ordinary purchaser, and between which there is usually little to choose in regard to wholesomeness or nutrient value. They are, however, required to be distinguished as separate articles of commerce, and as a result the imitation article has improved in quality and has a large and legitimate sale at a price which is certainly cheaper than would be the case if the distinction had not been insisted on by law and margarines had been allowed to compete with butter under the same or a similar name. The adoption of this principle has been to the advantage of the purchasing public, and particularly to the poorest members of the community, and in a broad sense is to the advantage of public health. It deserves to be remembered, however, that butter and margarine legislation in this country was largely brought about by the determination of the traders affected to act together in their own interests. This consideration is sometimes lost sight of by manufacturers of other foods, who are aggrieved by what they consider to be the malpractices of their competitors, and complain of the inadequacy of the law and the inactivity of public authorities. A particularly instructive part of the discussion was that which showed the active coöperation which takes place in some foreign and colonial administrations between the authorities and certain associations of traders, which are willing to help themselves in controlling and maintaining the purity of the foods which they prepare.

◆

Syphilitic Diseases of the Nervous System and the Biological Syphilis Reaction.

THE differential diagnosis of diseases of the nervous system often presents problems of great complexity, and long experience is required in order to arrive at correct conclusions. The etiological factor frequently suggests certain lesions, the correctness of the inference being proved by further investigation. One of the most important causes of organic diseases of the nervous system is syphilis, and the treatment adopted may naturally be based on the knowledge that a patient has previously suffered from that malady. It is possible, however, to lay too much stress on a history of a former venereal disease. We publish in this issue an abstract of an address on the Diagnosis of Syphilitic Diseases of the Nervous System delivered by Dr. F. W. MOTT at the clinical and pathological section of the Birmingham Branch of the British Medical Association in which attention is drawn in a forcible manner to this matter. He points out that in such a widespread disease as syphilis coincidence as well as cause is of very frequent occurrence. Therefore, as he says, in making a diagnosis the question has to be determined whether the fact that the patient has had syphilis, or even presents at the time of examination signs of active syphilitic lesions, is a coincidence, or whether it bears a direct or indirect causal relationship to the nervous symptoms of which he complains. This, however, is a problem that in many cases can only be solved by ascertaining the result of antisyphilitic treatment Again, granting that syphilis is a causal agent, the date of the primary infection will have to be ascertained, for the line of treatment to be adopted will largely depend upon the time that has elapsed since the specific sore appeared. Dr. MOTT gives as an example diffuse cerebral syphilis which occurs within four years of infection. The early diagnosis of this condition is of the most vital importance, for it is amenable to antisyphilitic treatment which if adopted in the early stages arrests or ameliorates the disease, while occasionally, though rarely, a cure may be hoped for. On the other hand, general paralysis, although of syphilitic origin, does not as a rule appear until ten years after infection, and is then not responsive to antisyphilitic remedies.

The remark that correct diagnosis is essential for satisfactory treatment is a platitude which applies to all branches of medicine. When the treatment largely depends upon one particular factor, such as the causal agent of the disease, every resource possible must be adopted in order to attempt to elicit the exact state of affairs. A progression of symptoms and an assemblage of signs frequently enable a correct judgment to be formed, but in many circumstances other methods have to be employed, chemistry and the recent developments of bacteriology holding the chief places amongst such auxiliary weapons. To be enabled to determine a syphilitic taint with certainty is obviously of prime importance, and the recent researches on the serum diagnosis of syphilis, or as it is sometimes termed the Wassermann reaction, have aroused much attention, and numerous observers have recorded their results. In THE LANCET of May 29th we published four papers on this subject written respectively by Dr. ALEXANDER FLEMING, from the Laboratory of the Inoculation Department of St. Mary's Hospital; Dr. JAMES M'INTOSH, from the Bacteriological Laboratory of the London Hospital; Dr. C. H. BROWNING and Dr. IVY MCKENZIE, of the University of Glasgow; and Mr. H. W. BAYLY, from the Bacteriological Laboratory of St. George's Hospital. In addition, we published an article on Auto-inoculation and Reinfection of Syphilis by Mr. J. HUTCHINSON. These papers form a mass of much valuable original work and tend to place upon a sound foundation a means of diagnosis which cannot but prove of the greatest assistance to the ordinary methods. Dr. MOTT, in discussing various conditions which might be mistaken for those caused by syphilis, indicates the worth of the Wassermann reaction and also of the microscopic examination of the cerebrospinal fluid. He likewise gives a description of the technique of the reaction, and therein lies one of its disadvantages—the test can only be performed by an expert worker in a well-found laboratory. Not only are the details of the method very complex, but as originally described the specific material was obtained from the liver of a syphilitic fœtus, which is obviously not always easy to procure. In order to be of general application, therefore, it is necessary that the test should if possible be simplified. A perusal of the contributions we have mentioned will show that to some extent this has already been accomplished. WASSERMANN believed that the reaction was a specific one which could only be brought about by using an extract of a syphilitic organ. It was subsequently demonstrated by LEVADITI and others that it was unnecessary to procure a syphilitic extract, as the reaction could be obtained by extracts from normal livers and hearts and many other tissues and organs. Then LANDSTEINER proved that the substances on which the test depends were of the nature of lipoids and were soluble in alcohol, so that alcoholic extracts of various organs could be well adapted for the purpose. Further, as originally performed, it was thought necessary to immunise an animal against the blood corpuscles of some other animal, such as by injecting the blood corpuscles of an ox into the circulation of a rabbit, whereby the blood serum of the rabbit became hæmolytic to the blood corpuscles of the ox by virtue of the presence in the serum of an immune body plus the normal complement. The normal complement was removed from the serum, after withdrawal from the rabbit, by heat and there was thus left in the rabbit's serum the immune body, which by itself would not dissolve the red corpuscles of the ox. The addition, however, of a small amount of guinea-pig's serum which contained complement at once restored the hæmolytic properties. This complicated procedure was somewhat simplified by BAUER, who took advantage of the fact that there exists in normal human serum a hæmolytic amboceptor for sheep's corpuscles, which did away with the use of the hæmolytic rabbit's serum, still, however, requiring guinea-pigs' blood as complement. HECHT proceeded further and employed the natural hæmolytic amboceptor for sheeps' corpuscles present in human serum, and also as his complement that present in fresh human serum. As Dr. FLEMING points out, HECHT made the serum to be tested supply the complement as well as the hæmolytic amboceptor. Dr. FLEMING, taking advantage of these observations, has perfected a technique which is more simple and better suited to clinical requirements. For a description of his process we must refer our readers to his paper, as the details are too long to reproduce here, but his method appears to us to be an advance on previous procedures.

The general adoption of the biological syphilis reaction will doubtless prove of great practical value in the diagnosis of diseases of the nervous system of doubtful origin. The conclusions already arrived at are suggestive and instructive, and further investigations will enable physicians to derive valuable information from the results obtained by their co-workers in the laboratory. As with other biological and bacteriological tests, although a marked positive reaction is of value—in the present instance it is a certain sign of a syphilitic infection—a negative result does not always indicate that no infection exists or has existed. It is singular that in primary syphilis the reaction may fail to appear. If a positive reaction has been obtained the indication naturally is that energetic antisyphilitic treatment should be at once adopted. Dr. M'INTOSH believes that sufficient experience has not yet been obtained in order either to give a definite opinion as to the influence of treatment on the reaction, or to say to what extent the reaction can be used to indicate whether sufficient treatment has been given or not, for the results obtained seem to differ in almost every case. Further investigation, then, is necessary before the amount of reliance which can be placed on the test can be correctly estimated, but the information already obtained designates the method as bearing the same important relationship to doubtful cases of nervous diseases that bacteriological tests do to tuberculosis.

Chronic Intestinal Stasis.

AT the meetings of the American Surgical Association and of the American Medical Association now being held in America two important papers have been read by Mr. W. ARBUTHNOT LANE. One of these—on the interesting subject of "The Operative Treatment of Fractures"—was read before the Medical Association and will be found published on another page of the present issue. The second, which was read before the Surgical Association, dealt with the operative treatment of chronic intestinal stasis, a condition which had not been treated by operation by anyone before Mr. LANE undertook its surgical treatment. The attention of surgeons of other countries has now been directed to his methods, and some of them have followed his example, and we summarise here his views and practice. The importance of chronic intestinal stasis runs little risk of being exaggerated. All who have studied and written on this subject freely acknowledge that the accumulation in the bowel of fæcal material is productive of most serious results, both immediate and distant, and that it deserves the careful attention and treatment of the physician, but it is only within recent years that the suggestion has been made that operative measures should be undertaken for its relief. That the large intestine is of less value than at first sight might appear is now acknowledged by many. METCHNIKOFF has suggested that to the presence of the large intestine is due much of that chronic poisoning of the whole body which hastens the onset of old age or, indeed, which may be looked upon as old age itself. To it he ascribes most, if not all, of the degenerative processes which are characteristic of old age, for on them depends that loss of elasticity of the several tissues which is its main quality. It must be acknowledged that these opinions have not met with complete acceptance by all, but nearly all agree that they are founded on a definite basis of fact. Quite independently of the work accomplished by METCHNIKOFF, Mr. LANE has been led to adopt very similar views, and he has had the courage to follow the leading afforded by the natural deductions. He had noticed both at operations and in the post-mortem room that in cases characterised by persistent and intractable constipation numerous adhesions exist within the abdomen, accompanied by malpositions and displacement of the abdominal contents, so that the displaced organs become fixed in their new situations; and from these observations he was led to conclude that the obstinate constipation existing in these cases was directly connected with the displacement of the viscera. He showed that the displacement of these organs, especially of the several parts of the large bowel, produced kinking at the flexures, with the result that the contents experience considerable difficulty in passing through the narrowed portions, while the accumulation of the fæces between the flexures led to dilatation of those portions of the bowel, and by the sagging thus occasioned intensified the sharpness of the constrictions. In this way would be produced a condition of chronic fæcal accumulation but little amenable to most, if not all, of the ordinary medicinal methods of treatment On a bowel such as this most of the purgatives contained in the Pharmacopœia would have little effect, and what small effect they might produce would last but a short time and perhaps be followed by even more troublesome constipation.

This is the condition of affairs looked at from the point of view of the peristalsis of the bowel, but its true importance is only fully recognised when we consider the effect produced by the absorption of the poisonous constituents of the intestinal contents. The true function of the large intestine is the absorption of water from the fæces. For many years the absorbent power of the large bowel was under-estimated; although nutrient enemata were regularly administered most physicians were more than a little doubtful if any large proportion of the constituents of these enemata was absorbed by the rectum. But careful observation of recent years has shown that the power of absorption possessed by the large intestine is very great; the quantity of fluid which can be absorbed by it is measurable by pints in the day. This power of absorption being acknowledged, it is practically inconceivable that, with the water which is taken up from the bowel, there should not also be absorbed many soluble substances. Now it is certain that the decomposition products existing in the large intestine are many and their quantity great. In health the short duration of the stay of the contents within the large intestine is sufficient to prevent any more than a moderate amount of absorption of these toxic products. But if for any cause the passage of the fæcal material through the bowel is delayed the amount of toxic products absorbed must be greatly increased. In civilised life there are several factors which tend to diminish the rapidity of the onward progress of the contents of the large bowel, and chief among these is probably to be put the long continuance of the erect posture in civilised life. While the savage, though standing, walking, or running for several hours a day, assumes between whiles the recumbent posture, civilised man stands or sits in an upright position for more than 16 hours a day and only assumes the recumbent posture during the time spent in bed. In the upright position the cæcum and the ascending colon are very unfavourably placed for the onward progress of their contents. The ileum pours its liquid fæces into the cæcum and gravity steadily opposes its passage onward, so that these portions of the large intestine form, as it were, a kind of cesspool, the emptying of which is irregular, and even when it occurs it is seldom complete. The assumption of the recumbent position, especially if the body is turned from one side to the other, does much to assist the emptying of the first portion of the colon, and thus it is certain that in uncivilised man the many positions assumed during the day do much to assist the intestinal peristalsis. And it is quite probable that the food of uncivilised man was more favourable on the whole as a stimulant to the bowel wall than the products of modern kitchens, though this is another point altogether. The effect on the cæcum and ascending colon of chronic intestinal stasis, however produced, is definitely harmful; the viscera undergo much dilatation, and the cæcum is forced down into the pelvis. Similar dilatation of the rest of the large intestine also follows, and according to Mr. LANE numerous adhesions form, the presence of which modifies greatly the shapes, positions, and activities of the various portions of the large intestine.

Such being the mode of production of this chronic inactivity of the bowel, we turn to the symptoms ascribed to the absorption of toxins to which the constipation gives rise. The chief symptoms are headache, a feeling of physical and mental lassitude, an inability to perform the ordinary duties of life, much mental misery and distress, and the want of control over the temper which makes these patients unhappy, and unpleasant not only to themselves but to those about them. Various nerve irritations appear; migraine and other neuralgias torment the patient, and by their presence intensify the mental discomfort from which they are already suffering. Auto-intoxication possesses still another power of harm; it has a definite effect on the resistance of the individual to the entry of harmful organisms. Mr. LANE even considers that tuberculosis may find an efficient aid in its entry into the body in the weakening effect of these intestinal toxins, and he claims that the examination of a large number of children affected with chronic tuberculous disease of joints has shown the presence in them of unmistakeable signs of auto-intoxication. Among these he includes the condition of the skin which becomes thin, inelastic, and abnormally dark. It is recognised generally that the peculiar tint of the skin in chlorosis is definitely dependent on chronic constipation, and various other changes of colour of the skin also own a similar origin. The amount of cutaneous staining varies greatly, according to Mr. LANE, with the type of individual. In light-haired patients a very advanced stage of auto-intoxication may exist and yet it may be unaccompanied by any obvious staining of the skin, while in dark-haired people the pigmentary modifications show themselves early. Other signs and symptoms of chronic intestinal stasis might be mentioned—all those, indeed, that usually mark prolonged constipation, but we will assume that the condition can be recognised, and come to the important question of treatment.

There is little room for dispute as to the facts of the absorption of intestinal products from the undue retention of fæcal material within the bowel, though opinions certainly differ widely as to the significance to be attributed to them. While some will think that the results of auto-intoxication are of the highest importance, many will be inclined to minimise the damage produced by the toxins absorbed and will be inclined to ascribe to other causes the symptoms credited by Mr. LANE to chronic intestinal stasis. It is, however, when we come to treatment that the greatest divergence of opinion will be found to exist, and it is on this portion of the subject that the novelty of Mr. LANE'S opinion mainly rests. He agrees, of course, that surgery has nothing to say until medical and mechanical methods of treatment have been tried and have failed. When, however, all the usual medical and mechanical methods for the relief of this chronic constipation have been tried Mr. LANE holds that the aid of a surgeon should be invoked, and various degrees of operative interference are recommended by him corresponding to the various degrees of severity of conditions existing. In some cases he has obtained considerable success by the mere division of constricting bands, and most surgeons who have had much experience in abdominal surgery will agree that cases do occur, though they are not common, in which a very intractable chronic constipation has yielded to the division of a constricting band. When the case is more severe, and mere division of adhesions will not suffice, Mr. LANE employs one or other of two more radical measures. The simpler of these is the division of the ileum near its attachment to the cæcum, and its transplantation to the sigmoid flexure, so that the intestinal contents no longer traverse the whole of the large bowel, but take a shorter route and pass only through a portion of the sigmoid flexure and the rectum. The more liquid nature of the fæces is sufficient to prevent any accumulation, and the previously troublesome constipation disappears at once, and with it, Mr. LANE tells us, disappear also all the serious symptoms which resulted from it. The skin clears and gains its normal colour, the mind of the patient is relieved from the anxiety and irritability which formerly interfered with its normal action, and the temper of the patient shows definitely the good which the operation has done. There are, however, some cases which Mr. LANE considers are not adequately treated by this operation of transplantation of the ileum, and in these he considers it necessary to excise the whole of the large intestine except the sigmoid flexure and the rectum, an operation of no great difficulty in itself but one accompanied by a large amount of shock, a matter of especial anxiety in subjects so much debilitated as most of these patients are. The same beneficial results follow upon the success of the larger procedure, and in addition there is no risk of any of the intestinal contents passing backwards in the cul-de-sac formed by the large bowel.

We cannot doubt the benefits ascribed to these operations by Mr. LANE, who has shown the medical profession many of his successful cases, but we think that hardly sufficient stress has been laid on the question of the risk of the operation itself. We have not been able to find any very definite statements as to mortality of operation; but deaths have occurred, and it would be well if we could see at a glance the exact effects of the operation with regard to mortality. The whole question must depend on whether the risks of persevering with medicinal treatment would be less than those of an operation. Are the dangers and discomforts of chronic intestinal stasis sufficient to justify the recourse to operative procedures in which the risk to life is by no means slight? It must be acknowledged that in this country the number of those surgeons who accept Mr. LANE'S views on this matter is comparatively small. Abroad they have met with more recognition, but in most countries it seems to be felt that sufficient data are not available for coming to a decision. We are sure of these things—that the evils of chronic intestinal stasis have not been fully recognised, and that the condition needs more attention than it often receives. The mere administration of a purgative and a few instructions as to diet are often considered to be sufficient treatment for chronic constipation which may have lasted many years. This unenterprising policy should not continue. On the other hand, although Mr. LANE has done good service in bringing forward the methods he advocates, and has shown extraordinary perseverance in the face of much opposition in advancing our knowledge of the capability of operation on the large bowel, we doubt if he has yet proved his case as to the frequency with which such extensive operations as excision of the large intestine are required. In other words, we want to know more of the risk of the operation so as to decide how large a number of cases should fall into the class where operative procedure is justifiable.

Hospital Sunday, 1909.

THE annual collection of the Metropolitan Hospital Sunday Fund will be made on Sunday, June 13th, and on the eve of the event we again express the hope that the appeal in the places of worship of all denominations in and around London will arouse a free and generous response. We know that the liberality of many congregations is taxed on frequent occasions, perhaps weekly, on behalf of deserving causes, but we urge the claim of the hospitals of London as one of paramount importance, worthy to be met by a donation exceeding the usual weekly offering. As a number of persons leave London at the end of the week in order to spend Sunday elsewhere we trust that they will be mindful also of the needs of the Fund. Many of them may attend worship on Hospital Sunday at places where no collection is made on behalf of this great distributing agency of London's charity, but it will give them little trouble to send their gift direct to the office of the Fund at 18, Queen Victoria-street, E.C., if they have omitted to entrust it to a friend for addition to the offertory.

In enjoining upon all that they should give generously and that they should treat Hospital Sunday as a special occasion, we are not unconscious that the present year is likely to be one of exceptional need for our charitable institutions, and that the benevolent coöperation of all will be required even more than in past seasons in order to maintain the Fund at its usual high level. THE LANCET holds no brief for Government or Opposition, and expresses no views on political questions from a party point of view, but we need not therefore ignore the fact that the financial proposals of the Chancellor of the Exchequer, whether justified or not by our needs and our circumstances, must seriously affect our voluntary hospitals. Under those proposals many will find their contributions to

Imperial taxation increased materially, and we do not shut our ears to statements which have been freely made that some at least of those affected may have to recoup themselves by diminishing their contributions to charity. If they are compelled to do this, and if the hospitals suffer thereby with other charities, then it behoves all who are not driven to such an unfortunate point of penury to put forth an additional effort to make good the loss involved. We have referred only to those obliged out of necessity to curtail their generosity. Others may feel disposed to do so, but we trust that they will dismiss the thought from their minds as an unworthy one. We feel sure that upon reflection they will realise that any effort of self-denial, any decision to forego a temporary and fleeting luxury, or even some much desired pleasure, would be preferable to allowing their personal loss to be transferred to those noble institutions whose cause we are pleading. The hospitals of London, if they crave for aid in their financial necessities as a visible and substantial token of public recognition of the great work which they carry on, have no reason to complain that their usefulness is not held in high esteem. Indeed, the main reason of their perpetual appeals for help lies in the increased and increasing appreciation bestowed upon them and in their desire to prove themselves worthy of it. They have to strive to do more each year because each year more is expected of them. And the help which they receive should be proportionate to the growing arduousness of their task.

The report of the Royal Commission on the Poor-laws affords in numerous passages proof of the huge burden cast upon the rates by the sickness or premature deaths of parents in the humbler classes of society, to which subject Mr. BURNS also referred in the eulogy of modern medicine with which he declared the Tuberculosis Exhibition open last week. We would remind the public that the work done in the hospitals tends, directly and indirectly, to prevent and diminish the accumulation of that burden, and that what the public gives in charity is to no small extent repaid to them by the hospitals and by the unpaid work of their medical staffs. A committee appointed by the Home Secretary for the purpose recently issued a report upon the provision of a rapid and effective service of ambulances throughout the metropolis. In our special supplement published on behalf of the Metropolitan Hospital Sunday Fund we pointed out that the holding of this inquiry showed the importance attached to the work of the hospitals and to the promotion of such a service, but that its institution in accordance with the recommendations made would mean no small increase in the number of cases brought to hospitals of all kinds for treatment. But already aid to the sick and injured is supplied in every hospital of the metropolis to the full extent of its financial power, and we urge upon all that the supply should be made as nearly equal as may be to a demand likely to be augmented considerably. The supply will never exceed the demand, for the hospitals aim at one ideal—"Efficiency"; and efficiency for them is inseparable from constant movement forward along that path of scientific progress, the pioneers of which work in the hospital wards. Medicine desires to place, through the generosity of those who are wealthy by comparison, the benefits of therapeutic and surgical skill and of nursing, all of the highest order, at the disposal of those whose poverty would otherwise set the boon beyond their reach, leaving them to die unaided. Therefore, the demand for aid never lessens, and in urging it on behalf of the Metropolitan Hospital Sunday Fund we appeal to all, whatever their financial circumstances, to give generously, in the assurance that their gift, whether great or small, will be wisely and economically administered, and that it will do its full share in maintaining those great charities among which the Metropolitan Hospital Sunday Fund annually distributes its resources.

Annotations.

"Ne quid nimis."

THE MODERN TREATMENT OF FRACTURES.

WE publish this week an address entitled The Modern Treatment of Fractures, delivered by Dr. Lucas-Championnière, the President of the International Society of Surgery, before the Cardiff Medical Society on Friday last, June 4th. Compared with the progress which has been made in most departments of surgery, the treatment of fractures has lagged far behind. The rules laid down in the dawn of medicine held good until a very recent date, and as certain of these were based on theory rather than on practice it is not surprising that the best results should be withheld from those practitioners who will not allow the possibility of modification. It is still taught by many surgeons, and was until recently universally believed, that the essential principles of the treatment of a fracture are that the fragments of the bone should be replaced exactly in their former position, and that they should be there held fixed for a sufficient time to allow the fragments to become firmly united. These are the directions which are found repeated, the words merely being varied, in nearly every textbook of surgery or treatise on fractures up to the present time, and in most cases without addition or qualification. There are, however, considerations which give rise to some doubt as to the correctness of these generally received principles. The formation of callus is essential to the union of a bone, and it is certain that the chief factor in the determination of the amount of callus formed is the amount of movement of the fragments. Further, it cannot be accepted as essential that the fragments must be replaced in their original position with anatomical accuracy. The introduction of the Roentgen rays produced shocks in the minds of not a few surgeons, for they found that fractures which had seemed to be accurately reduced were often in a by no means perfect position when they were scrutinised by the new exponent. Various slight displacements were seen to be present, and yet the limb was as useful as its fellow. It cannot be too firmly laid down that the true test of the success of the treatment of a fracture is *functional activity*. To have the fragments of a bone in perfect position will not serve unless the utility of the part is also completely restored, and if the utility of the limb is perfect the precise positional relation of the fragments matters little or nothing, cosmetics apart. The introduction of the x rays has not been wholly beneficial to the operating surgeon, for in the first place skiagrams are very liable to [illegible] and secondly, the fact that the fragments [illegible] lead the unlearned [illegible] unsatisfactory. Dr.

consists in early massage of the limb and mobilisation, commenced within the first 24 or 48 hours. These he holds to be of capital importance, for by their aid sufficient callus is formed to unite the fragments firmly, the absorption of effused blood and serum is favoured, the mobility of the limb and of the neighbouring joints is assured, by all of which convalescence is hastened. It is often objected to this method that it is, or at least may be, very painful, but the statement is made chiefly by those who have never seen the method employed. No one who has had experience of the treatment of fractures by massage and mobilisation can doubt that this method often diminishes the amount of pain which the patient suffers, not only during the period of consolidation of the fracture but also after the fracture has united. The treatment by fixation has a great tendency to cause stiffness in the muscles of the limb and in the adjoining joints, while the breaking down of adhesions caused by prolonged rest is often one of the most trying portions of the whole treatment. This part of the pain resulting from a fracture is entirely avoided by Dr. Lucas-Championnière's tactics, for when the pieces of the broken bone have united the functional activity of the limb is unimpaired. The results of this treatment fully justify its adoption in suitable cases, but there must be care in its employment. Splints cannot be absolutely discarded, for when the tendency to displacement is very great they will be required after the limb has been massaged. In other cases splints may be used with advantage but removed each day while the massage is given. In short common sense must be employed to control the unrestrained use of massage and mobilisation, for it is not difficult to imagine cases where, from the conditions in which the patient is situated, or from other considerations, the full carrying out of massage and mobilisation is impossible. The views expressed by Dr. Lucas-Championnière have not been accepted by the majority of our surgeons, and this may have been due to the wrong application of his teaching; but there are many indications that the new methods are gradually gaining ground as we learn more of their range of utility. To those of our readers who are unacquainted with the treatment by massage and mobilisation the reading of Dr. Lucas-Championnière's address will afford much interest, and they might supplement this information by the study of the volume which he published in 1895. The careful practice of the doctrines inculcated will, we believe, be followed by an appreciation of their value.

THE "INDIVIDUAL CUP" AT THE HOLY EUCHARIST.

SOCIETY, in Mr. Gladstone's phrase, must "stand the recoil of its own principles." It must equally be prepared to modify its usages in the light of better knowledge. Of this truth the Church of Scotland has just been affording illustration at its General Assembly, before which a committee reported that on medical, among other, grounds the use of the individual cup at the Communion table ought not, in the opinion of the said committee, to be prohibited. In the course of a debate on the same subject at last year's sitting of the same Assembly it transpired that the falling-off in attendance at the Communion table was largely accounted for by the reluctance of many of the congregation to apply their lips to the cup which had already been similarly touched by fellow communicants whose personal cleanliness, nay, whose exemption from contagious disease, was more than doubtful. Gruesome details of the physical "unpreparedness" of these communicants to take part in the mystic rite were freely set forth, while more serious still was the suspicion that the common cup might be used by this or that communicant suffering from malignant disease, incipient or developed, and that positive danger to health, nay to life itself, was incurred by the use of that cup passed on to the next communicant. Impressed with these revelations the General Assembly appointed a committee to consider the whole question in all its aspects, medical and other, with the result that it has just had to take action on that committee's finding, by which, as already stated, the communicant should not be "prohibited" from using his (or her) "individual cup." An amendment, based on a "minority report," was subsequently proposed that the "innovation" in question should not be permitted and that the communicant should be allowed to take his (or her) chance of the "septic touch," or worse, as had hitherto been "the practice of the Church of Scotland." To this a counter motion was made that "the movement for change should be discouraged as strongly as possible without absolutely forbidding it." On a division being taken this motion was carried, "amid applause," by 240 votes to 145; so that in future the "individual cup" may be used by those who have fortitude enough to disregard the haply wounded *amour propre* of their fellow communicants or the possible imputation of thinking unduly of their corporeal interests at a peculiarly spiritual observance of the Church. How the innovation may work out in practice remains to be seen. Meanwhile, the question is one of a class from which no Church is altogether exempt—a movement, medically inspired, having long been agitating the Latin communion for the more frequent renewal of the holy water kept at the entrance of cathedral or basilica, the said water being so contaminated by the touch of the poorer among the faithful as to become an active medium for the propagation of disease.

THE PROPOSED NEW EALING HOSPITAL AND ITS STAFF.

THE unfortunate controversy which raged for some two years around the visiting staff of the Hampstead General Hospital, and which did much to upset the popularity of an undoubtedly useful institution, is now happily a thing of the past, and the success of a recent festival dinner on behalf of the hospital was such that we may hope it will enjoy a career of extended utility under its new *régime*. There are, however, indications that in another London suburb similar trouble is in danger of arising, and in the interests both of the sick poor and the medical practitioners in that locality it appears to us desirable to make a statement of the facts as they have come before us. Ealing has for a number of years possessed a Cottage Hospital of some 30 beds staffed by local practitioners, with the assistance of a London surgeon who has attended to perform operations requiring exceptional skill, and we believe that the professional conduct of the institution has been entirely satisfactory to its beneficiaries and subscribers. Money is now being raised to rebuild the hospital and enlarge it so as to accommodate about 50 beds. The appeal for funds for this purpose has met with fair success, and a considerable contribution has been offered by the King Edward's Hospital Fund for London, but on the embarrassing condition that the hospital shall be conducted on the lines of a metropolitan general hospital. We understand that the King's Fund has not entered into a detailed explanation of this condition, but in the light of the policy pursued by that body during the negotiations for the amalgamation of the Hampstead and North-West London Hospitals it is not hard to foresee that the Fund anticipates the replacement of the Ealing local staff by a body of metropolitan "consultants." It is also not hard to foresee that any such procedure will be resented by the majority of the Ealing practitioners on exactly the same grounds as it was resented at Hampstead, and we are not at all sure that the Ealing Hospital will weather such a storm as is likely to break around it when its subscribers realise the choice which they will have to make. It is on this account that we call attention to the matter before it is too late for friendly settlement, as we conceive it to be to the advantage of the hospital that its supporters should realise the responsibilities which unqualified acceptance of the subsidy of the King's Fund will probably entail, and we advise any medical practitioners who may be interested in the result to lay the case of local staff *versus* London staff before the people who will be called upon to make the decision. Our own feeling is that the local conditions in Ealing are such that the hospital is unlikely to thrive if the services of the local practitioners are dispensed with. The suburb is a well-defined municipal entity with a fair amount of local spirit, and if its medical men were driven into an attitude of corporate hostility or even of indifference to the success of the now expanding hospital we fear that the institution may not only cease to expand but even cease to exist. Again, it may not prove an easy matter to obtain an efficient London staff in the face of medical opposition in the district, and taking all the circumstances into consideration Ealing would do well to ask itself before it goes any further, "Shall we support our new hospital ourselves and run it in our own way with a staff resembling that of the old Cottage Hospital, or shall we accept a handsome subsidy towards the building from King Edward's Hospital Fund and be prepared not only to say good-bye to our local staff, but to lose their sympathy with the future work of the institution?" Hampstead had to answer that question, but we are not at all satisfied that Ealing can give the same answer without severely damaging its local hospital. We think that a staff of local physicians and surgeons, strengthened by one consultant physician and one consultant surgeon from outside will best meet the particular conditions of the case.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

A SUMMARY of the report of the Society for the Prevention of Cruelty to Children was given in THE LANCET of May 29th, p. 1577. It is a satisfactory document recording the progress and work of the society during the 12 months immediately preceding its entry upon the twenty-fifth year of its existence, and the meeting which celebrated that anniversary afforded no less cogent proof of the high position won and maintained by the society. The meeting referred to was held at the Mansion House, with the Lord Mayor in the chair; among those who addressed it in praise of the good work done by the society were the Lord Chief Justice of England, Mr. Curtis Bennett, second to none in experience as a London magistrate; and Mr. Herbert Samuel, M.P., the energetic young Minister largely responsible for the recent Children Act, who declared his indebtedness to the unfailing assistance of the society's director in the preparation and discussion of that measure. The names of the supporters of the society are proof of the triumph achieved by persevering work, in the teeth, sometimes, of inert obstruction and active opposition. The attitude of the legal profession, for example, has not always been one of sympathy towards the society. Twenty years ago it used to be a commonplace opinion among members of the Bar who criticised its proceedings that the society must be mistrusted, and its evidence submitted to closer scrutiny than that accorded to other prosecutors, because the society always assumed the guilt of the defendant, refused to abandon that assumption, and fought tooth and nail for a conviction in order to obtain subscriptions from the benevolent by quoting records of success. It may be suggested that perhaps this was true then, and that experience has taught those responsible to adopt a more judicial position. We doubt, however, whether this is the case, and we are inclined rather to believe that the society in its early days, as now, satisfied itself that a case was one which in the interests of justice ought to be taken up, and then laid its evidence fairly before the tribunal, leaving accused persons to make good their defence exactly as they are left to do in other criminal trials. We observe, at any rate, that Mr. Curtis Bennett spoke of the society at the Mansion House as prosecuting only when it was absolutely necessary, and that Lord Alverstone, who said he had been present at the birth of the society, declared that for one case of excessive zeal or of imprudence on the part of its inspectors there were hundreds of cases never heard of by the public in which they had brought relief to suffering children. His lordship also spoke of the share taken by the society in promoting the upbringing of children to be healthy, happy, strong, and willing citizens of the empire. This is an aspect of the society's work and of its aspirations which brings it closely into sympathy with the medical profession, and it must not be forgotten that in nearly every important and contested case which the society is compelled to ventilate and to fight out before judge or magistrate it is almost certain to be the medical evidence which turns the scale. The negligent or brutal parent or guardian, through his advocate, struggles to secure acquittal. The evidence of neighbours or of servants is belittled and ingeniously ascribed to motives of personal hostility to the defendant, to lack of accurate observation, or to any other cause than the desire to tell the truth. The medical witness goes into the box and it is at once found that against him no suggestion of animus can be raised, and that his evidence is of facts seen and described by a scientific observer. He tells the jury of the condition in which he found the child when he first saw him, giving particulars of his weight, his general physical and mental condition, and the marks on his body, and he points out where the matters thus noticed corroborate the story told by other witnesses of cruelty or neglect. He then recites the facts observed on a subsequent occasion, when, perhaps, after a few days only, there has been rapid increase of weight and improvement of condition, evidently due to the substitution of ordinarily proper treatment for neglect and ill-usage. Upon such an occasion the guilt of the accused is usually established beyond the possibility of doubt. On the other hand, if the weight of medical testimony is on the side of the person charged he has the full benefit to be derived from the absence of any motive to espouse his cause, and in that case also when such evidence turns the scale there can be little question as to the justice of the decision arrived at.

SYPHILITIC SCIATICA.

No form of sciatica remains more rebellious to treatment than the syphilitic unless it is recognised and treated specifically. It is a variety of sciatica the relation of which to preceding syphilis is much more likely to impress itself on the physician if it occurs in the secondary stage than if in the tertiary. The possibility of syphilis being causally related to sciatica must always be taken into account, though the interval between the two be a long one. In the *Lyon Médical* for December, 1908, M. Favre and M. Roubier describe the case of a man aged 37 years, who contracted syphilis at the age of 24, and who for three months had suffered agonising pain in the typical sciatic distribution on the right side. Treatment by accepted methods, physical and medicinal, had proved of no avail. On the affected side the knee-jerk was exaggerated, the tendo achillis jerks were present and equal, there was no affection of the sphincters, and no loss of sensibility was discoverable. Under treatment with 60 grains of potassium iodide daily and injections of mercury biniodide a complete and apparently lasting cure was effected in 18 days. Syphilitic sciatica may appear as a secondary or as a tertiary phenomenon. In the former case it occurs from six to 12 months after the chancre, and according to Fournier is rarely complete, being usually limited to a segment of the limb; its evolution is capricious, it is liable to exacerbations and remissions, nocturnal paroxysms being specially apt to occur; it yields readily to antispecific treatment. The latter presents the classical symptoms of sciatica, with spots painful on pressure; it is peculiarly intense and persistent, and, like sciatica of the secondary stage, frequently worse at night; irregular anæsthesias may occur and sometimes muscular atrophy. Pathologically, it is due to a syphilitic sclero-gummatous neuritis, in some cases possibly to a syphilitic osteitis or periostitis. In diagnosing between a pure trunk sciatica of this nature and sciatic neuralgia from syphilitic disease of the spinal roots it is worth remembering that exaggeration of the pain by coughing or sneezing is strongly suggestive of the latter condition. In this, further, we should expect to find anæsthesias of radicular distribution, occurring commonly in the following order: fifth lumbar, first sacral, second sacral, and fourth lumbar, and finally a lymphocytosis of the cerebro-spinal fluid.

THE TEMPERATURE, RAINFALL, AND SUNSHINE OF MAY.

THE month of May is, taking the average for a long series, the most sunny month of the year over Ireland, Scotland, and the western and north-western counties of England, but over the eastern half of England, June, July, or August generally supplies the greatest number of sunny hours. The month which has just elapsed has been unique for the extraordinary allowance of sunshine, its record not only beating easily that of all the preceding Mays since the inauguration of the automatic sunshine instrument in 1881, but being higher in some parts of the kingdom than during any month of the 12 since the record began 28 years ago. This is all the more remarkable, as during the month of April there was also a great excess, that month affording more sunshine over a considerable portion of the kingdom than any of the 28 preceding Aprils. It has frequently been one of the most striking features of the sunshine during the past few years that the London record, as represented by Westminster, has been steadily diminishing the extent of the minus difference between the metropolis and the resorts on the south coast. The figures in the table show the same tendency in a rather marked degree, Westminster recording 134 hours more than the average, while the excess at most places on the south coast is less than 110 hours. The aggregate in London, 297 hours, or rather more than nine and a half hours per day, was considerably higher than those in the North of England, and also exceeded that at Margate, while it was only three hours less than the record at Yarmouth. At Greenwich the figure was 326 hours, or only ten hours less than that at Brighton. It will be seen that there was very little difference between the totals in any part of the South of England, inland places such as Bath and Tunbridge Wells getting about the same number of hours as the coast. At the very top of the scale stand Hastings and Folkestone, with the respective total of 340 and 341 hours, equal to 11 hours per day, and at the bottom are Manchester and Aberdeen with 200 hours, equal to six and a half hours per day. As would naturally follow from such uninterrupted sunshine, the number of rainy days was very small. There was, in fact, scarcely any rain during the first three weeks of the month, and it is open to question whether the undoubted benefit arising from the brilliant sunshine was not in a certain measure counterbalanced by the lack of the usual number of showers to cleanse the atmosphere. The great dryness was certainly very detrimental to some of the ordinary farm produce. In spite of some very sharp and damaging frosts during the earlier half of the month the mean warmth of the whole period was slightly in excess of the average in nearly all places represented in the table, the warmest spot of all being London, with a mean temperature of 54·3°. The mildest nights, however, were experienced at Torquay and Llandudno, where the mean minimum temperature was 1° higher than in London, and between 4° and 8° than in the North Midlands. Round about the middle of the month the range of temperature between the early morning and the afternoon was unusually large, but the mean diurnal range for the month was not at all high considering the general state of cloudlessness. In this respect such widely separated places as Scarborough, Margate, Hastings, Torquay, and Llandudno shared alike, their mean range being no more than 14°.

* A day with at least 0·01 inch.

INTRACRANIAL HÆMORRHAGE IN THE NEW-BORN.

THE occurrence of hæmorrhage from the cerebral veins which lie beneath the dura mater is one of the common causes of infantile cerebral hemiplegia and epilepsy, spastic paraplegia, diplegia, and other conditions for which when they come under observation relatively little can be done. To Cushing of Baltimore belongs the credit of working out the problem of their treatment from the point of view of early surgical intervention, and the results he has obtained demand the most favourable consideration. The superior longitudinal sinus receives from 10 to 12 veins from the superior cerebral surface on each side. The presence of these large vessels, in relation more particularly to the coronal and lambdoidal sutures, suggests the possibility of their injury in the displacement and overlapping of the cranial bones during parturition. The symptoms of the condition are those of cerebral compression, and it seems to be characteristic of many of these cases that localising signs are absent. In the *Boston Medical and Surgical Journal* of April 22nd Dr. Torbert, of the Boston Lying-in Hospital, describes two typical cases. One concerned the infant of a primipara, delivered by low forceps after an 18 hour labour, where everything seemed to have gone well till the fifth day. Then the child refused to feed and appeared stupid. His limbs became stiff, although they were still moved. The anterior fontanelle became tense and ceased to pulsate. A lumbar puncture was done and a teaspoonful of blood-stained fluid obtained. It was decided safe to delay until the result of catharsis could be seen, but the child sank and died a few hours later. The whole cerebral hemisphere on the right was then found to be covered with a fresh hæmorrhage, which extended below the tentorium. In the second case the symptoms appeared on the second day, the child being cyanosed, with twitching of the right side of the face, and the anterior fontanelle bulging. In the course of a few hours death ensued and the left hemisphere was found covered with recent blood-clot. The only hope for beneficial results lies in immediate operation. Last year Cushing reported nine cases with four recoveries; in 1905 he published four cases with two recoveries. In every case the diagnosis is made entirely on symptoms of cerebral compression, which vary somewhat as the compression is supra- or infra-tentorial.

THE FORTHCOMING HEALTH CONGRESS AT LEEDS.

PROGRESS in sanitation and hygiene depends in a great measure upon the education of the public in regard to such matters, and the attitude of municipal corporations towards health problems and their solution may react either for good or for evil upon public opinion. The Lord Mayor of Leeds, Alderman F. J. Kitson, is therefore to be congratulated upon the keen interest which he shows in the forthcoming Health Congress organised by the city and University of Leeds, with the coöperation of the Royal Sanitary Institute and the Royal Institute of Public Health. It will be held from July 17th to 24th. On May 18th a meeting was held in the town-hall of Leeds under the presidency of the Lord Mayor, when he issued an urgent appeal to all leading citizens to assist in the social side of the Congress, and pointed out that matters of health ought to receive the attention of the whole of the community. The President of the Congress is Colonel T. W. Harding, J P., D.L., a member of the Royal Commission on Sewage Disposal, and the general secretaries are Dr. J. Spottiswoode Cameron, medical officer of health of Leeds, and Mr. R. E. Fox, the town clerk of that city. According to the preliminary arrangements, the sections will include: Preventive Medicine, of which Dr. Arthur Newsholme, Principal Medical Officer to the Local Government Board, is the president, and Dr. R. V. Clark and Dr. Charles Porter are the secretaries; Industrial Hygiene, with Dr. B A Whitelegge, C.B., Chief Inspector of Factories to the Home Office, as president, and Dr. F. W Eurich, Dr. A. G. Wilson, and Miss Maynard as secretaries; Child Study, the president of which is Dr George Newman, Principal Medical Officer to the Board of Education, and the secretaries Dr. J. R. Kaye and Miss Alice Ravenhill; and Biology and Chemistry, to be presided over by Dr. A. S. F. Grunbaum, professor of pathology and bacteriology in the University of Leeds, with Dr. T. Orr as secretary. There will also be an Engineering and Architectural section. A conference of municipal representatives will be presided over by the Lord Mayor of Leeds, and a conference of veterinary surgeons and of sanitary inspectors will also be included in the programme. The address of Dr. Cameron, the secretary, is 41, Park-square, Leeds, from whom further particulars of the Congress may be obtained.

BENZOIC ACID IN CRANBERRIES.

WHEN certain substances usually referred to as chemical preservatives are found to be normal constituents of foods, a serious difficulty may arise in the event of legislation being directed to the prohibition of the preservative. Salicylic acid, it is true in small quantity, has been found in some fruits and in wine, and recently benzoic acid in very appreciable quantity has been found in cranberries. The dried berry contains as much as 0·45 per cent., and when warmed the free benzoic acid is expelled and may be caught as a crystalline sublimate. We do not remember to have heard that cranberries have been banned on account of producing injury to health; but certainly some authorities have, on the force of experiments made with benzoic acid or benzoates put in food administered to the human body, condemned the use of these substances for preservative purposes. The conclusion, however, has been attacked by other observers, who claim that in moderate quantities, though sufficient for preserving purposes, benzoic acid or the benzoates are harmless. It would be interesting to find whether cranberries in large doses are injurious outside any ordinary effects upon the stomach; though if they proved not to be so, the explanation might be that benzoic acid from natural sources produces no injurious results, while when it is prepared artificially or by synthesis, perhaps because a foreign constituent is present, its exhibition is not so innocuous.

TROPICAL ADENITIS AND PLAGUE.

IN a paper published in THE LANCET of June 5th, p. 1595, by Dr. R. Leonard Ley, attention was directed to some cases of illness characterised by chronic buboes of some size, especially in the groin, which had come under his observation, the patients having seemingly contracted their illness in India or elsewhere in the Far East. This form of adenitis, in Dr. Ley's opinion, is "due apparently to an as yet unrecognised organism," which may have been transmitted to man by animals, such as horses and mules. He also throws out the suggestion that possibly the disease may bear the same relation to bubonic plague that cow-pox does to small-pox, and that it may in the same way as cow-pox be transmitted to man. For some years it has been well known that many natives of the East suffer from non-venereal buboes. Manson and Scheube have described such cases of tropical adenitis, which are said to be generally of a chronic kind, excision of the enlarged glands hastening the cure. As yet no satisfactory explanation has been forthcoming as to the origin of these cases, though Manson thinks they may be due to some virus which has gained an entrance to the body through some small wound, abrasion, or insect bite, on the leg or foot. Some competent bacteriologists have made careful search for a specific organism in the enlarged glands, but so far without success. Cantlie and Hewitt as well as other observers have discussed the bacteriology of such cases and the possible relation of this form of adenitis, called by some "climatic bubo," to bubonic plague. Cantlie has regarded such cases as a modified manifestation of plague which he named "*Pestis minor*," regarding it as often being a precursor of a more serious plague epidemic. But most experts now hold the view that there are no adequate reasons for regarding oriental adenitis as having any connexion whatever with true plague. Glandular enlargement is a frequent accompaniment of tropical disease, and it is therefore possible that the cases which Dr. Ley and others have met with are not due to one specific organism alone, but may be instances of the secondary effects of various diseases contracted in the tropics. In our opinion no evidence has been brought forward to justify the view that these cases of chronic non-venereal bubo contracted in India and the Far East, described by Dr. Ley and others, have any relation at all with true bubonic plague. Nor have we received any evidence that horses or mules are susceptible to plague, or that the inoculation of plague bacilli into these animals produces any local disease communicable to man in the way that small-pox when inoculated into the bovine animal produces a local disease transmissible to human beings.

THE CHURCH ANTI-VIVISECTION LEAGUE AND HOSPITAL SUNDAY.

WITH the approach of Hospital Sunday our attention is, not for the first time, directed to the pamphlets sent out by a body bearing the title of the "Church Anti-vivisection League." Everyone has a right to publish his opinion, and even to try to bring over others to his way of thinking, provided that by so doing he will do no harm to others and that he does not bolster up his own opinions by means of perversions of the truth. But the provisions are of importance. We have had to comment upon the literature issued by the Church Anti-vivisection League upon a previous occasion, when it became evident that the honorary secretary had no idea of what constitutes "proof." It is now evident from a publication before us that the League has no idea of what constitutes truth. Anti-vivisectors are fond of quoting Tennyson as an opponent of vivisection. He undoubtedly was so, but he also wrote that "A lie which is half the truth is ever the blackest of lies." We err on the side of charity when we say that the pamphlet now in question is half the truth, and though we have not space to go through the misrepresentations in detail, we will note one or two. On page 1 of the pamphlet, under the heading "1908, Hospital Laboratories and the Royal Commission," there are given some figures from the Parliamentary Return of Experiments on Living Animals in 1907. Figures are quoted and then we find the following sentence, "In the remaining 1199 experiments anæsthetics are alleged to have been used in the initial operation ......" Why does the League say "alleged"? It can only be because it wishes to make the readers of the pamphlet believe that vivisectors licensed under certificate B or B + E E or F tell lies when they return their experiments as being initially performed under anæsthetics. Further down we find, speaking of experiments without anæsthetics, "It is true that the vivisectors claim that the great majority of these experiments are inoculations or hypodermic injections, but it is also noticeable that this year, as usual, the Inspector inserts the qualifying expression 'and some few other experiments,' words which may cover anything." Now the Inspector expressly states on page 5 of the return which is being reviewed, when speaking of experiments without anæsthetics, that they "are mostly inoculations, but a few are feeding experiments, or the administration of various substances by the mouth or by inhalation, or the abstraction of a minute quantity of blood for examination. In no instance has a certificate dispensing with the use of anæsthetics been allowed for an experiment involving a serious operation. Inoculations into deep parts involving a preliminary incision in order to expose the part into which the inoculation is to be made are required to be performed under anæsthetics." Why does the League omit to quote this passage, and why does it say that "vivisectors claim that the great majority of these experiments are inoculations," implying by these words that they are not so? Most of the rest of the pamphlet is taken up with Colonel Lawrie's evidence given on March 25th, 1908, about an experiment by Dr. W. H. Gaskell which he (Colonel Lawrie) had witnessed on July 7th, 1894. Those portions of Colonel Lawrie's evidence which are not convenient to the arguments of the League appear to be omitted altogether. Furthermore, the evidence of Dr. L. E. Shore and other witnesses before the Royal Commission, all rebutting Colonel Lawrie's statements, is not given, the pamphlet merely saying, "It is hardly necessary to say that Dr. Gaskell and his assistants contradict Colonel Lawrie's assertions." The whole pamphlet is a mis-statement of facts. If the League acted up to its name it would remember the apostolic dictum—"the Church of the living God, the pillar and ground of the truth."

THE ANTITOXIN TREATMENT OF MALIGNANT ANGINA AND PARALYSIS IN DIPHTHERIA.

WHILE the value of antitoxin treatment in diphtheria is well established, doubt is entertained as to whether the malignant sore-throat and the paralysis of the disease are amenable to this remedy. M. J. Comby has warmly recommended the antitoxin treatment of diphtheritic paralysis,[1] but in France other writers, and in this country Dr. J. D. Rolleston, whose experience of the disease at the Grove Fever Hospital is great, have denied its value. Dr. Rolleston suggests that the good results claimed by M. Comby were due not to the treatment,[2] but to the fact that late diphtheritic paralysis in diphtheria is, as a rule, benign, and that since the introduction of antitoxin more patients have survived to suffer late paralysis. Moreover, Dr. Rolleston pointed out that the repeated administration of antitoxin recommended by M. Comby is not innocuous, but may produce rigors, vomiting, and collapse, and profuse urticaria. Recently these results have received more attention in consequence of the researches of Richet on "anaphylaxis," a term by which he describes the increased sensitiveness which animals present under certain conditions to a second dose of toxin. At a recent meeting of the Société Médicale des Hôpitaux of Paris, M. H. Méry, M. B. Weil-Hallé, and M. Parturier reported excellent results at the Pavillon Hospital from administration of antitoxin in increasing doses (*sérothérapie intensive*) in the malignant angina and paralysis of diphtheria. In 1908 they were struck with the number of children who succumbed to paralysis or to syncope after disappearance of the membrane. From Jan. 1st to Oct. 1st 622 children were admitted, of whom nine died from paralysis and three from malignant angina. They therefore endeavoured to obtain better results by modifying the method of treatment. M. Louis Martin advised them to give repeated injections of antitoxin during convalescence in cases of severe angina without waiting for the appearance of paralysis. At the same time they increased the dose during the acute period of the angina. They gave 40, 50, and 60 cubic centimetres on consecutive days. The membrane disappeared and the throat became clean; then they gave a dose of from 10 to 20 cubic centimetres every day or every other day. If paralysis occurred in spite of this preventive treatment they continued and even increased the dose of antitoxin, so that some patients received in all more than 500 cubic centimetres. From Nov. 1st, 1908, until March 1st, 1909, during which this treatment was adopted, they did not lose a single case of malignant angina, and no patient died from paralysis or from late syncope (248 patients were admitted from Oct. 1st to March 1st). Paralysis was observed in 18 cases, but usually was mild. However, in three cases of malignant angina of the most severe type they were not able to prevent paralytic symptoms of an alarming character. In the severe cases subcutaneous injections of strychnine, sparteine, and adrenalin were also given. Under the latter the arterial tension appeared to rise. They did not think that there was any danger of anaphylaxis from repeated doses of antitoxin, for anaphylaxis usually results from administration of a small dose of antigen to an organism saturated with antibody. With large doses of antigen the danger is less. In the discussion which followed M. Netter said that he had found repeated injections of antitoxin useful in malignant diphtheria, though he had never given doses so large as those mentioned. He did not deny the danger of anaphylaxis, two cases of which he had observed, but that never prevented him from giving repeated injections of antitoxin in diphtheritic paralysis. He also praised the administration of suprarenal extract, which he gives by the mouth in severe diphtheria, having learned this treatment from Dr. Rolleston. M. Netter explained the good results on two grounds: in animals poisoned by diphtheria toxin there are manifest alterations in the suprarenal capsules; and in severe diphtheria the blood pressure is very low. In the heart failure of other infectious disease, such as scarlet fever, adrenalin has also given him "marvellous" results. He usually gives from 10 to 20 drops in the 24 hours in five or six doses.

[2] THE LANCET, August 4th, 1906, p. 322.

THE VALUE OF MILK-SUGAR IN THE ARTIFICIAL FEEDING OF INFANTS.

IN order to increase the calorie value of diluted cows' milk used as a substitute for breast milk in the feeding of infants it is usually recommended to add cream and sugar, and since cream is too expensive for the poor to employ, and is, moreover, less easy to obtain free from bacterial contamination, sugar in some form is more generally utilised. Owing to the fact that the natural sugar in the milk of all animals is lactose, this sugar has been regarded as the best to use if possible, although its greater cost compared with other sugars, such as glucose, cane sugar, and malt sugar, is again an obstacle to its general use. According to the observations of Rubner, 243 parts of milk-sugar have an equal heat value with 100 parts of fat, and the milk-sugar has therefore been utilised in such proportions as to make up for the deficiency of fat and sugar in diluted cows' milk. Recently some few authorities have questioned the value of milk-sugar added to milk dilutions, and Dr. Richard Weigert of Breslau gives in the *Berliner Klinische Wochenschrift* of May 24th an interesting summary of these opinions, as well as a record of his own observations made at one of the municipal dairies in that city. Prechtl in 1901 appears to have been the first to write against the use of milk-sugar, on the grounds that it promoted the growth of gas-forming bacteria, and that it rendered the milk less easily digestible by separating the alkalies and calcium from their combinations with phosphoric acid. Finkelstein has also regarded milk-sugar as injurious, especially in dyspepsia, and further states that it is much inferior to cane sugar and to malt sugar as an addition to the diet. Czerny and Keller have also expressed the view that lactose is of minimal influence upon growth. As a result of his own observations, Dr. Weigert concludes that the addition of milk-sugar in 10 per cent. solution as a diluent for cows' milk is without influence upon the weight curve of infants, that it is without beneficial effect upon digestive disturbances, and may hinder the return to normal when given to infants with frequent slimy motions. Dr. Weigert found no advantage in employing milk-sugar solution over simple dilution with water or with some simple diluent such as barley-water. He points out that the matter has an importance apart from its scientific interest in regard to pædiatrics, since the expense to the authorities in supplying pure milk-sugar to the municipal dairies is by no means inconsiderable.

THE VICEROY OF INDIA UNDERGOING PASTEUR (ANTI-RABIC) TREATMENT.

IT is reported that Lord and Lady Minto have been obliged to undergo the Pasteur treatment in consequence of a pet poodle having been bitten by a mad dog, which bit two members of the subordinate staff. The poodle having been fondled by both Lord and Lady Minto, and its saliva being infectious if rabies is present, caused the Viceregal medical adviser, Colonel W. R. Crooke-Lawless, R.A.M.C., to summon assistance from the Pasteur Institute at Kasauli. The treatment of rabies has been very effectually carried out in India during the past seven years. There are two Pasteur Institutes in India—we believe they are the only British Pasteur Institutes in existence, and each under a director appointed from the Army Medical Service and financed by the Government of India. Details of the last report of the Kasauli Institute were published in our issue of May 29th.

IRRITANT WOODS.

AN interesting case was reported in these columns a few years ago, in which an acute irritation of the skin was traced to contact with satinwood. The dermatitis broke out amongst the operatives at a saw-mills where satinwood was being cut up. The sawdust has since been carefully chemically examined with a view to discover a definite principle to which the irritating effects might be ascribed. The investigation was undertaken by Dr. Auld, of the Scientific and Technical Department of the Imperial Institute, and some preliminary results have been placed in a paper read before the Chemical Society. By suitable treatment an oil present to the extent of 1 per cent. was extracted, which, however, did not appear to possess irritant properties. A small quantity of an alkaloid, however, was obtained which, reduced from its solvent, appeared in prismatic crystals. It is apparently an alkaloid not yet included in the ordinary category and has been called chloroxylonine. It yields definite salts and behaves with certain reagents in a similar way to the great alkaloid family. Further experiments are being made and further supplies of the alkaloid are in course of preparation, but there appears to be little doubt that it is capable of producing dermatitis similar in character to that produced when the wood from which it is derived comes into contact with the skin.

THE SCOTTISH PRISON COMMISSION.

THROUGH the retirement of Colonel McHardy the chairmanship of the Scottish Prison Commission is about to become vacant, and we trust that the Government will take advantage of this occasion to remove what has long been felt as a grave anomaly in prison administration in Scotland —namely, the absence of a medical member on the Prisons Board. It is somewhat singular that the northern kingdom, which has always enjoyed an enviable fame in psychiatry, should in this respect lag behind England and Ireland, where for some considerable time past there has always been a medical Commissioner of Prisons. The question was carefully considered by Lord Elgin's Departmental Committee on Scottish Prisons in 1902 and a strong recommendation was adopted in favour of following the same policy in Scotland. The committee reported that it was "much impressed by the fact that in the great majority of instances where difficulty has arisen in the management of prisons, questions have been involved which require for their determination experience in medical requirements and practice, and yet that no member of the Board possesses any medical qualification"; and it expressed very strongly the view that the presence of a medical member would greatly improve the administration and would increase the confidence of the public. It can hardly be doubted that the Government will feel bound to give effect to this authoritative recommendation, and that the vacant position will be filled by one of the distinguished physicians who, we understand, have offered themselves as candidates for it.

OPHTHALMOLOGY AT OXFORD.

THE sixth annual post-graduate course in ophthalmology in connexion with the Faculty of Medicine of the University of Oxford will be held at the Oxford Eye Hospital from July 5th to 17th. On July 15th and 16th there will be a meeting of ophthalmic surgeons, when addresses and demonstrations will be given. The main idea of the course is to demonstrate the whole range of ophthalmology, and the day's work will be divided among lectures, demonstrations, and practical work. It is hoped that some 500 cases will be present for demonstration. Among those who are to give special addresses and demonstrations on the last two days of the course are, besides well-known British ophthalmic surgeons, Dr. Darier of Paris, Professor Deutschmann of Hamburg, Professor Dufour of Lausanne, Professor Greef of Berlin, Dr. Motais of Angers, and Dr. Remy of Dijon. Dr. F. W. Edridge-Green will give a demonstration of some new phenomena connected with colour vision, Mr. N. Bishop Harman will show his new diaphragm test for vision, Mr. A. W. Ormond will give a demonstration of the Mendelian theory in its application to ophthalmology, and Professor Arthur Thomson will give a stereoscopic demonstration of the structure of the eye. The course will be illustrated by the lantern. Fee for the course, £5 5*s.* Gentlemen attending the course will be provided with board and residence at Keble College at the rate of 7*s.* 6*d.* a day during the second week, but during the first week lodgings must be secured. Further particulars can be obtained from Mr. Robert W. Doyne, Margaret Ogilvie's Reader in Ophthalmology in the University of Oxford, 30, Cavendish-square, London, W. Details of the newly constituted diploma in ophthalmology will be found at p. 1727.

"PAINFUL HEELS."

IN a recent issue of the *New York Medical Journal* Dr. I. D. Steinhardt has published a useful paper on a subject which has not received much attention—painful heels. Many patients come under professional care complaining of severe pain and tenderness in the heels on walking, and the nature of the malady is not understood and therefore is not properly treated. A frequent cause of painful heels is acute inflammation of the os calcis with formation of new bone, which is sometimes described as exostosis of the os calcis. Usually there is a history of gonorrhœa, gonorrhœal rheumatism, gout or rheumatism, or traumatism in certain cases of weak feet. Males are more often affected than females. The gonorrhœal form usually occurs between the ages of 18 and 45 years; the gouty and rheumatic at and after the age of 40 years; the form associated with weak feet may occur at any age. In a case of the gonorrhœal form the following changes were found. On cutting into the soft parts of the heel, which in appearance and on palpation showed nothing abnormal, the tissues were found to be œdematous and the muscle discoloured. On the inferior surface of the os calcis the bone was abnormally prominent and rough in the region of the tuberosity. The bone was also very brittle and could easily be removed with a sharp spoon. Some pieces were decalcified and sections were cut. They showed granulation tissue consisting chiefly of spindle cells. From pieces of the bone a culture of the gonococcus was obtained. The adjacent tissues were infiltrated in all directions by broad bands of bone. The process was evidently an ossifying periostitis due to the gonococcus. Osteitis of the os calcis may also be due to other organisms; streptococci and staphylococci have been found. The patient usually complains at first of general pain in the foot, which soon becomes localised in the heel, while over the tuberosity the pain on pressure is exquisite, indeed it is often so great that the patient cannot put his feet to the ground. Radiography shows one or more spicules protruding from the os calcis, and periostitis of the surrounding bone or a much enlarged tubercle with surrounding periostitis. In the gonorrhœal variety treatment of the primary disease will help to cure the osteitis. In the gouty and rheumatic forms these diatheses must be treated. In the traumatic form associated with weak feet strapping may be applied and followed by the wearing of well-fitting plates, but operative treatment may be necessary. For this an incision is made in the middle line of the foot two inches or two and a half inches long, terminating about half an inch behind the tubercle of the os calcis. Retractors are inserted and the exostosis at the bottom of the wound is chiselled away and the bone is scraped with a sharp spoon until the surface becomes smooth and seems healthy. The wound is washed out with normal saline solution and closed without drainage with interrupted catgut sutures After two weeks the feet may be put to the ground, and after three weeks the patient should be able to walk.

THE King has granted to the undermentioned His Majesty's Royal licence to accept and wear the decorations which have been conferred upon them by His Highness the Khedive of Egypt, in recognition of valuable services rendered by them:—To Mr. Henry Pottinger Keatinge, M.B. Durh., F.R.C.S. Eng., director of the School of Medicine and of the Hospital of Kasr-el-Aini, the Imperial Ottoman Order of the Medjidieh, Second Class; and to Mr. Frank Cole Madden, M.D. Melb., F.R.C.S. Eng., professor at the same School of Medicine, the Imperial Ottoman Order of the Medjidieh, Third Class.

A TELEGRAM from the Governor of Hong-Kong to the Secretary of State for the Colonies stated that 11 cases of plague and 12 deaths were reported during the week ending with the month of May. A telegram from the Governor of Mauritius, received at the Colonial Office on June 4th, states that there were two cases of plague reported during the week ended June 3rd and two deaths from the disease.

MEDICAL GOLFING SOCIETY.—The annual tournament of the Medical Golfing Society will be held at the Burnham Beeches Golf Club on Thursday, June 24th. Play will be 18-holes, match play, *v.* bogey under handicap. There will be three prizes in each of two divisions —the senior competition being for those with a handicap of 12 and under, the junior for those whose handicap is over 12. The "Henry Morris" challenge cup and the Medical Golfing Society's gold medal will be competed for. There will also be a foursome sweepstake in the afternoon. Any person on the Medical or Dental Registers can join on payment of the annual subscription (4*s.*), which includes entrance to the tournament. Entries, accompanied by subscription and giving lowest handicap, should be sent to L. Eliot Creasy, 36, Weymouth-street, London, W., on or before Monday, June 21st. Conveyances will meet trains at Burnham Beeches station (G.W.R.). Cards may be handed in till 8.30 P.M.

INSTRUCTION FOR SCHOOL CHILDREN IN THE PRINCIPLES OF TEMPERANCE.

IT has long been realised by all who give thought to such matters that instruction on the subject of temperance might well be given by the teachers in our national elementary schools as a *part of the teaching of the elementary rules* of personal health. Hygiene is included as one of the regular subjects in which the students at the training colleges, who intend to become teachers, are now instructed in order to equip them for their future educational duties, and under this heading there would be given very properly information as to the value of food-stuffs, the effects of alcoholic beverages, and the consequences of intemperance to the individual, to the family group, and to the commonwealth. But while there need be no difficulty about instructing the embryo teacher, there has been considerable difficulty in deciding exactly what lines should be pursued by the full-blown teacher when he is asked to imp

which

Ther

of the lessons on temperance which is recommended by the department to be followed by the teachers of the scholars attending our elementary public schools, and the necessity for this syllabus is well explained in a brief prefatory note by Sir Robert Morant. At the present time some of our elementary schools have not on their staff teachers possessing the knowledge necessary to give instruction on temperance, and in order that the scholars might receive such instruction the services have been utilised of missionaries from various societies and organisations, and the classes have been allowed to count *towards* the *period* of secular instruction required by the Code. But these peripatetic teachers, though specially qualified to discuss their subject, have not always, says Sir Robert Morant, the particular qualifications required by the Code or any experience of methods of teaching suitable to their audience, while the courses of instruction have not seldom been found inappropriate to the purpose. In these circumstances, the Board of Education has come to the conclusion that an official syllabus should *be issued as a model to which all future teaching should* conform in general character, and to some extent in detail We print the syllabus *in extenso* :—

Section I.

EATING AND DRINKING: FOOD AND ITS USE.

2.

3.

4.

nation itself is undermined.

The syllabus is followed by a series of notes for the use of the teachers, devised to supply them with the information necessary for the elucidation of the catechism to which they are expected to submit their pupils. Under *Section I.* it will be seen that it is intended that the teacher should put questions ascertaining what are the foods in common use in the children's homes, and should explain to them the rough physiology of nutrition. Children will be taught the use of their food and the reason for the employment of the different kinds of food, and will hear also the arguments against the use of alcohol as a food. Under *Section II.* more stress will be laid upon the possibility of alcoholic beverages bringing about injurious changes in metabolism and affecting detrimentally the strength of the body and the power of work, while stress can also be laid under this section upon the effects of excessive drinking of alcohol by reference to the estimated mortality due to diseases owing to this origin In support of this part *of the syllabus* the teachers are furnished with tables compiled from the Registrar-General's Decennial Reports showing (1) the average mortality among occupied males (25 to 65 years of age) from alcoholism in various trades over a period of three years (1890–92); and (2) a comparison between deaths from all causes and from alcoholic diseases. A third table is also given showing the expectancy of life (that is, the average future duration of life dated from the age in question): (*a*) in the general population of England and Wales *based on the experience of 1891–1900*; (*b*) in persons insured in a large number of the principal life offices based on the experience of 1863–93; and (*c*) in various friendly societies and the United Kingdom Temperance and General Provident Institution. The first two tables show the risks run from alcoholism by inn-servants and inn-keepers, and the third shows how much more favourable is the expectancy of life in persons abstaining from alcoholic beverages. The tables, of course, are not intended to be presented to the children. *In Section III.* there are laid down the lines for certain instruction which is not intended to be given to childr

12, and its moral is

not only may have ba

individual but also

drinker, unhappiness

large.

The notes to the syllabus, which we have thus briefly epitomised, make up an extremely *interesting and* valuable document. The statements and the inferences can be supported by high authority, the greatest possible care

ously been given to the exact form in which the
are put, so that while the great physical and
ons are clearly brought out, there should be no
r an accusation either of exaggeration or of

It goes without saying that a debate could be
er some of the statements made in presenting the
aspect of the drink problem, but the general pro-
that the prosperity of any nation depends upon its
and that if a large number of these workers damage
pacity by excess in alcoholic drinks that nation sooner
will degenerate and fall behind others (being unable
ully to compete with more sober and temperate races)
in a convincing form. It has been alleged that some of
nperance teaching given in the past which was repre-
as scientific has, in fact, fallen short of a scientific
ard as regards accuracy in stating facts and caution
awing inferences. "In some cases," says Sir Robert
nt, "it appears that attempts have been made to
ort the incontrovertible general arguments against the
se of stimulants by suggesting that alcohol inevitably and
ariably has deleterious consequences when taken as a
erage in any condition whatever. The proposed proof of
s proposition sometimes included in lectures on temper-
ce given in public elementary schools occupied time that
ight have been better employed for the purpose of
nculcating temperance on broad intelligible grounds and as
scientific argument rested on somewhat precarious founda-
ions." Not a few medical men will endorse and welcome
this reasonable pronouncement.

We consider that the Board of Education in drawing up this syllabus, and in thus supplying teachers with the necessary information for the exposition of most important matters, has taken the right course to provide security that the teaching should be both accurate in its statements of facts and suitable in its manner of presentation to the audience. It must, of course, often happen that children who are practically underfed will receive instruction upon the choice of diet, which will create a rather grim situation; and other children will have the faults of their parents made apparent to them in a manner which may make it difficult for them to obey the decalogue. These are, however, matters which must not be weighed against the general good that will accrue to the community if the school children of the nation are taught lessons of self-control and the appalling misery and wastefulness due to the alcoholic habit. We are glad to see the words of warning with which Sir Robert Morant closes his prefatory remarks. "The teacher," he says, "should carefully avoid anything, whether in the details or in the methods of dealing with them, calculated to excite morbid curiosity or fear. Instruction in the subject of 'Temperance' should itself be temperate, and should make a sober appeal to such reasoning capacity as a child possesses and to the ideas of decent self-respecting and dutiful living which every good teacher endeavours to present to and cultivate in the children under his charge."

THE
SEVENTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

WITH the closing of the proceedings on Wednesday last week the impression was left that the International Congress of Applied Chemistry in London had been a conspicuous success. The meeting at all events has served to remind the community of the great importance of chemical science in its application to the arts and industries and to the welfare of the human race. Considerable credit is due to the organisation committee for the smooth way in which the work of the various sections proceeded. It must have cost considerable effort to bring to a satisfactory issue the business of a congress having such a comprehensive subject before it for discussion as applied chemistry. The fact that there are few departments in human affairs which are not affected at some time or other by the application of chemical science rendered the programme of subjects for discussion a necessarily full one. In spite, however, of the situation created by this plethora, the attempts put forward to preserve some system and order succeeded well, and altogether the outcome of the Congress will be an advance in the cause of science and scientific

Pressure on our space last week made it impossible
anything more than a rapid sketch of the proceedings,
although in that sketch prominence was given to subjects
which come more or less within the precincts of medical
science. This week we conclude our account with reference
more particularly to the proceedings in the Sections of
Pharmaceutical Chemistry, of Bromatology, and of Hygie
respectively.

PHARMACOLOGY.

Amongst the papers which attracted considerable interest in the Pharmaceutical Chemistry Section was one by Mr. E. M. HOUGHTON, M.D., Ph.C., on a Proposed International Standard for the Physiological Assay of the Heart Tonics of the Digitalis Series. As the result of much painstaking experimental work of a physiological kind, the author is led to the following conclusions: (1) It is impossible to determine the value of the heart tonics of the digitalis series by chemical assays; (2) the toxicity of these products warrants that every effort should be made to present preparations of them as uniform in value as possible; (3) experiments upon animals have demonstrated conclusively that the variation in the physiological action of some of these products is extremely great; and (4) that the section should appoint an international committee to determine and recommend the best method of physiological assay of the heart tonics of the digitalis series and to erect an international standard, a "heart tonic unit" to express the physiological value of the pharmaceutical products of this series. In his paper the author described his method of physiological assay, the result of
nearly 15 years of labo[illegible] possible solution of
the problems.

"Standardisation" w[illegible]
Mr. P. W. SQUIRE and Mr. C. M. C[illegible]
important question of [illegible]
medicines. In their [illegible]
examples calling fo[illegible]
motion was carried [illegible]
an international inquiry sho[illegible]
securing: (1) greater uniformity in the co[illegible]
potent drugs and the means for determining the [illegible]
(2) approximation in the pharmacopœias of the world to
common standards of activity. This paper received strong
support from a paper by Mr. PETER MACEWAN, Ph.C.,
F.C.S., and Mr. GEORGE P. FORRESTER, which, referring to
the variations in the activity of certain toxic drugs, de-
manded an international inquiry.

In the same section Mr. W. HARRISON MARTINDALE read
a very complete paper on the various organic arsenic com-
pounds. He urged further work from the therapeutic point
of view. Broadly, it is shown that inorganic arsenic taken
internally is slowly eliminated—it remains stored up in the
system for a long time—but the same does not appear to be
true with regard to the organic compounds which have been
used medicinally. The ideal organic arsenic body should
pass away quickly from the region of the stomach, but, on the
other hand, for the treatment of diseases of the nature o
trypanosomiasis and syphilis, a slowly dissolving body wou
seem to be of importance so as to prolong the action on t
organisms. The relation of the constitution of these orga
compounds to their therapeutic action was discussed.

An interesting paper on the Toxicity of Acetanilide Mixt
was read by Mr. SEIDEL on behalf of Mr. WORTH H
It was shown that in the experiments upon both warm
cold-blooded animals caffeine was found to exert a
marked antagonistic effect so far as the heart-rate
cerned, but it had only very slight action upon the le
contractile power of the heart muscle. The antago
so very imperfect that it is probably of very little
relieving the heart distress of acetanilide poisoning
the popular belief in its efficacy. When given to t
animal (mice and guinea-pigs) it markedly incr
toxicity of acetanilide. On the other hand, sodium bi
was found to exert a greater influence than caffeine
acting the depressing effects of acetanilide.

These, with the interesting address given by th
of the section, Mr. N. H. MARTIN, on the History
Chemistry in its Relation to Pharmacy, formed th
tributions to this section.

BROMATOLOGY.

Standardisation was again the favourite topic
in this section, and it was interesting to hear
the efficacy of the food laws of various count

by their representatives. Dr. W. H. Wiley, *for example,* read a paper on Food Control in the United States. He described the system of adminstration in that country. After giving a detailed sketch of the national laws relating to foods he passed on to the State laws and said that practically all the States had laws of some kind bearing upon the control of foods. There were also many municipal laws applying to the inspection of restaurants, bakeries, dairies, &c., and to the sale of milk. He regarded the system of food control in the States as effective, and emphasised the value of a legislative authority deciding upon standards of purity.

Mr. F. W. Beck, solicitor to the Grocers' Federation, discussed the same subject from the point of view of this country, and pointed out that the objects which repressive legislation with reference to foods should have in view are the ensuring of wholesomeness and the prevention of fraud; [illegible] presence [illegible], against [illegible] fixing of standards, he thought, should not be used for mere equalisation of chemical constituents in foods, and still less should it be used for the purpose of establishing or maintaining one branch of industry at the expense of, or to the detriment of, another. From the public point of view he doubted whether the advantage gained in one direction by the fixing of standards for natural products is not more than counterbalanced in another by the lowering of the general average quality. He instanced, amongst other things, the depreciatory effect of standards upon the quality of milk and butter. Referring to the question of preservatives he drew a distinction between their use and abuse, and concluded by proposing what the constitution should be of a Board of Reference which from time to time might effectively deal with these matters.

On the other hand, Mr. O. G. Moor and Mr. W. Partridge urged that from the administrative point of view the setting up of standards would secure uniformity. They suggested that in the case of milk the public analyst in every district should publish the percentage of fats contained in the milk *supplied by the different dealers, whose names should be* attached to the report.

Mr. N. P. Booth said that the absence of a legal standard for chocolate meant that while the sale of certain chocolate preparations was prohibited in some other countries these wares were permitted to come without restriction to the English market. The actual amount of cocoa in chocolate varies enormously, and sometimes it was hardly present at all, and still the stuff was sold as chocolate.

The section seemed to be of the opinion that in the work of fixing standards the collaboration of manufacturers should be invited.

SYNTHETIC CHEMISTRY.

There were a number of papers on synthetic chemistry, although few of them related to synthetic remedies. In generalising upon the subject Professor Paterno of Rome pointed out how tortuous and indirect after all was the way by which the chemist synthesised a substance as compared with the great simplicity of Nature's methods. He thought, however, that organic synthesis would be made more direct as our knowledge advanced in regard to the changes effected by the action of light, of micro-organisms, of enzymes, and of catalytic substances.

Professor Haller of Paris referred to the influence upon certain branches of commerce which the discovery of the synthesis of camphor may have. He said that in regard to alizarin and indigo, *science and industry had incontestably* got the better of nature. The cultivation of madder had completely disappeared in the south of France and artificial indigo was a menace to the immense and numerous plantations of India, Java, and Guatemala. It would be rash, he added, to say that the same thing was going to happen in the case of camphor, for it was to be remembered that the fundamental substance used in producing artificial camphor—namely, the essence of turpentine—was limited in supply, and prices fluctuated considerably.

HYGIENE.

In the Hygienic Section Dr. J. Grosmann of Manchester drew attention to the present mode of sewage sludge disposal, which, he said, was not *only* objectionable from a hygienic point of view, but was absolutely against all economic principles. At Bradford a process had been inaugurated by which an appreciable amount of fat was obtained from the sludge, which found a market at about £7 *per ton.* The residual substance after the separation of this grease by distillation was a fine brownish-coloured powder without odour and sterilised. It showed on analysis a good manurial value, and was suitable *for mixing with other fertilisers* for agricultural purposes. He quoted the instance of a town of 100,000 inhabitants in regard to the economy of the process. In such a case the cost of working up the sludge would amount to £2610 per annum, whilst he calculated that the amount realised by the sale of the products would be over £5000, leaving a margin of close on £2500.

In the same section an interesting paper on the Chemical Evidence of Slight Sewage Pollution of Sea-water was contributed by Mr. H. A. Kenwood and Dr. F. N. Kay Menzies. The evidence suggested is of importance in view of the question as to whether sea bathing in water contaminated with human excreta involved risk to the health. There is also the *case of the pollution of shell-fish.* They found that the figures giving the free and saline ammonia furnish the only trustworthy chemical guide to the lesser degrees of animal contamination of sea-water; also that delicate corroborative evidence may sometimes be obtained from the presence of nitrites and phosphates; but the complete absence of oxidised nitrogen is compatible with recent pollution, and it is not always possible to obtain a definite reaction for phosphates when the contamination is marked. The free and saline ammonia figure remains of all the available tests hitherto suggested the most trustworthy and the most delicate, and they suggest that an ammonia figure much exceeding 0·002 per 100,000 is certain evidence of the sewage contamination *of sea water.*

In a paper by Mr. J. E. Purvis, Mr. G. H. Macalister, and Mr. E. Minnett experiments were quoted to prove that it was quite unsound to pour sewage directly into the sea or even into a tidal estuary. There was little doubt that the salt of the sea stopped the purifying action of the microbic scavengers and hence putrefaction was prolonged and the discharge remained for some time offensive. Ultimately offensive matter was probably destroyed by the oxygen dissolved in the sea water. It was urged that some preliminary treatment should be adopted before sewage was discharged into the sea in order to expedite the destruction of the complex compounds.

The sewage of the *motor-car, as the fumes may be called,* was a matter also dealt with in the Hygienic Section. M. Frenkel proposes to introduce a deodoriser consisting of a tube lined inside with platinised asbestos or porcelain. A mixture of air and motor fumes passed through such a tube was automatically burnt, the catalytic cell in the tube becoming incandescent in the process. The writer said that the acrid smell from motor-car engines was due to acrolein formed by the action of carbon monoxide on the unsaturated hydrocarbons.

The subject of poisonous industries was discussed in the same section. In his address to the section Sir Thomas Oliver said that occupation should be a means of life and not a cause of death. He was optimistic enough to believe that what chemistry had done for lucifer matches it could accomplish for pottery and paint, so that certain industries which had hitherto dragged in their trail a considerable amount of suffering and distress should become a means of healthy living.

Professor P. Bedson of Newcastle also contributed a paper on a subject connected with dangerous occupations—namely, the Inflammability of Coal-dust. He described a method and apparatus for the practical study of the question. It was found that coal-dusts differed very materially in their inflammability. The dust from brown coal was found to be the most readily inflamed, while bituminous coal-dust containing a high percentage of volatile matter came next in order of inflammability. Finely divided charcoal does not inflame under the conditions of the test. Damping the dust was found to raise the ignition point considerably and an admixture of silica with the coal-dust had a similar effect.

In the above and in the previous notes in our last week's issue of the proceedings at this most interesting and valuable Congress we have dealt mainly with medical matters. We have necessarily left out all reference to the highly technical papers which were discussed on such subjects, for example, as explosives, metallurgy and mining, the starch and sugar industries, the colour industry, and so forth, the importance of which, however, will be recognised.

l individuality, and a pioneer in France in the spread eaching of Pasteur and Lister.

Lucas-Championnière, who was received with great asm, briefly returned thanks to the assembled company or their reception of him and his family, and to the Mayor and Lady Mayoress whose guests he, Madame -Championnière, and their two daughters were. He rously pleaded old age as an excuse for not making a ch.

r. William Sheen, honorary secretary of the Lynn mas and Skyrme Fund, then made a brief statement as he constitution and results of the Fund. He stated how action in which Mr. Lynn Thomas and Mr. Skyrme were olved arose as far back as 1904. The first trial was in ecember, 1905, and the second in November, 1906. The aintiff, who claimed £2000 damages, was awarded £100, ut as the verdict carried with it costs the expense to the efendants amounted to such a total that after taxation, and after a contribution from the Medical Defence Union of over £900, there still remained to be paid £3200. Following a medical dinner which was held at Cardiff within a few days of the second trial, when about 130 medical men emphatically expressed their sympathy with the defendants, an appeal was made, and within a period of four months there was collected for a re-imbursement fund £1781. The result was that Mr. Lynn Thomas and Mr. Skyrme would receive about £800 each towards the expenses which they had incurred. The money had been subscribed by some 2000 medical men all over the country, no less than 200 being subscriptions of 2*s*. 6*d*.

Mr. Edmund Owen, in introducing Mr. Lynn Thomas and Mr. Skyrme to the presenter of the testimonial, congratulated all those responsible for the gathering upon its great success. In a manner which obviously went home to his hearers he dwelt upon the splendid way in which Mr. Lynn Thomas had stood by Mr. Skyrme. This fact had been recognised by the medical profession, and he felt that both Mr. Lynn Thomas and Mr. Skyrme had come well through a painful ordeal, and that the verdict of the courts was not that of their fellow practitioners.

Sir Alfred Thomas and Mr. Mansell Moullin having also spoken in testimony of the personal worth of those who were about to receive the testimonial, Mr. Lynn Thomas and Mr. Skyrme, amidst much applause, walked up the hall arm-in-arm to where Dr. Lucas-Championnière sat on the right of the chairman, and received from him the cheques resulting from the fund.

Mr. Lynn Thomas spoke first in acknowledgment of the presentation. He declared that the event would for ever be memorable to him as proving to him that he had retained the confidence of his fellows and bringing with it the assurance that an invisible hand would support members of the medical profession under wrongful accusations. He returned the warmest thanks to Dr. Lucas-Championnière for his presence there that evening, to Mr. William Sheen for his devoted labour in organising the fund, and to all those who had subscribed to it. Mr. Skyrme spoke in a similar vein, pointing out also that the issue of this case, in support of which the Medical Defence Union had paid no less a sum than £928, had been that both that society and the London and Counties Medical Protection Society had now made arrangements with insurance companies whereby, in consideration of a small annual subscription, the payment of the damages and costs in such actions as those in which he and Mr. Lynn Thomas had been involved would be paid up to a certain amount by the insurance companies.

Dr. D. R. Paterson then proposed "The Health of the Visitors," to which the Lord Mayor of Cardiff, Dr. Dawson Williams, and Dr. Squire Sprigge responded.

The Lord Mayor having warmly expressed his pleasure both at welcoming Dr. Lucas-Championnière to Cardiff and at being present on an occasion so gratifying to Mr. Lynn Thomas, Mr. Skyrme, and the medical profession generally, Dr. Squire Sprigge said that as the significance of the meeting had already been so eloquently indicated by previous speakers he would confine his words to one particular point —viz., the manner in which the appeal to the profession was made. That manner was wholly admirable. The statement of the case in the medical press was studiously fair, and every point made was, or could be, vouched for by high rgical opinion. The original letter of appeal was based nds without a touch of bitterness or personal recrimination in it, was signed by names eminent in the medical world as professors, consultants, and leaders generally, and received a remarkable scientific endorsement from the continent and the United States. The success of the movement was assured by the manner in which it was inaugurated no less than by the righteousness of the cause advocated.

Dr. Dawson Williams said that the movement which reached its final stage on that occasion owed nothing of its success to personal considerations. It was a movement to vindicate the right to freedom of thought. The claim to that right was no new thing, for it had led to the foundation of the mediæval universities, but it was appropriate enough that this most recent defence of the principle should have originated in Wales, for the people of the Principality had in comparatively recent times been impelled, by a punctilious adherence to that principle, willingly to make many sacrifices. In the exercise of the medical art freedom of thought implied freedom to act for the best, according to the best knowledge of the day. In conclusion, he said that he was commissioned to state that Dr. E. Rayner, treasurer of the British Medical Association, had intended to be present, but was detained in London by pressure of business. Dr. H. Davy, too, who when President of the Association, had taken a warm interest in the initiation of the movement, was also unfortunately detained at the last moment.

After the health of the chairman and secretaries of the dinner, which was in every way a most successful function, had been duly drunk the meeting dispersed.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS: EXHIBITION AT WHITECHAPEL.

An exhibition organised by this association was opened, as we have already announced, by Mr. John Burns, the President of the Local Government Board, on June 2nd at the Art Gallery, High-street, Whitechapel. The object of the exhibition, which is chiefly of a popular and educational character, is to bring home to the people the nature of tuberculosis, the extent of its ravages, and the possibility of its prevention and cure. To this end, popular lectures homely talks, and lantern demonstrations are given fro time to time during the period which the exhibition remai open—namely, till June 19th—and no charge is made admission. The success which follows such exhibitions been proved in America, and also in Ireland by the campa organised by Lady Aberdeen, and the country owes a of gratitude to the National Association for its pr exhibition and for its determination to carry on the throughout the Kingdom.

On entering the vestibule of the exhibition atten immediately arrested by the large posters of the asso with the heading "Symptoms of Early Consum These posters state that consumption is curable majority of cases if taken in hand early, and after deta symptoms which may point to consumption exhort to take prompt medical advice. It is to be hoped crowds, among whom are many working men an who attentively peruse these excellent posters, by the advice given. Almost directly inside the d exhibition, the walls of which are covered with m ing the statistics of tuberculosis and photographs o and overcrowded areas, are two models of a tenement as it exists in London. The first displ ture—if the tatterdemalion bed, the washstan basin, and the crazy chest of drawers can be so without an attempt to conceal its failings defaults. The actual dwelling which the fu represents was occupied by four people—fa and two children—and darkness and dampnes features. The next model shows the sa intelligence and a feeling for cleanliness have now transformed it into an inhab attractive dwelling. Gone are the paper-pa and where there was darkness, inevitab by stench and disease, there is now furniture wears a new aspect, and we feel that there is also an atmosphere of health in the general cleanliness and tidiness. Near to this exhibit are rough drawings showing the right and the wrong way to sweep a floor. One picture shows a woman sweeping a floor on which sits a baby, while the dust which the sweeper is raising with her broom almost chokes the child. The other shows the broom enveloped in a damp cloth and the child is playing happily without being subjected to the risk of disease from infected dust. Of course, it would be better if the child were taken [illegible] e in [illegible] and [illegible] the [illegible] How [illegible] ows [illegible] fecting another person at a distance of 25 feet, and the other the same patient coughing with his hand before his mouth, afterwards spitting into a piece of paper which he crumples up and throws into the fire. Not far off is a model cradle made out of a banana box with hammock mattress of unbleached calico, cretonne drapery, and muslin covering. This easily and cheaply made contrivance is a direct answer to the statement that the poor cannot afford cradles; the idea is to this extent far superior to the employment of a drawer—the usual substitute for a cradle—in that all the drawers which poor women have are generally badly wanted. This contrivance, which is similar to one shown in connexion with the Second International Congress of School Hygiene,[1] was sent by the Marylebone Health Society, which also exhibits a cheap apparatus for sterilising milk. All of these tangible and visible things have a more potent effect upon the minds of the really poor or ignorant than the scientific part of the exhibition, and nothing but good can come of this somewhat sensational way of proving to the populace that many features of daily life are dangerous. The exhibition of various kinds of food with notes on their dietetic value should also serve a useful purpose in the education of those whose daily fare is too often prompted merely by custom and who have never given thought to the economy of their food.

A special section is devoted to tuberculosis in children, and one of the most interesting exhibits in this department is a large model of an open-air school designed by Dr. Frederick Rose, assistant educational adviser to the London County Council. An eight-page pamphlet giving an account of the nature and scope of open-air schools, and details and estimates of the model can be obtained at the pamphlet stall in the exhibition. This model was originally shown at the Country in Town Exhibition held at Whitechapel in 1908.[2] The institution known as Lord Mayor Treloar's Cripple Home and College at Alton is represented by photographs showing how tuberculosis in children is treated, and the methods adopted in other institutions, including the Alexandra Hospital and the Salop Convalescent Home, are also shown in a similar manner and by models. One end of the main room of the exhibition building is fitted up as a ward of the Royal Victoria Hospital for Consumption at Craigleith, Edinburgh, and there is also a model showing the arrangements of the buildings and grounds of this institution. The hospital is connected with the Royal Victoria Dispensary for Consumption, which was started in 1887 with the object of combating tuberculosis and of affording a central institution towards which persons suffering from the disease might be directed. Sanatoriums of various kinds are well represented, and the models include the Seaforth Sanatorium, the Maitland Cottage Sanatorium at Peppard Common, the Frimley Sanatorium, and the Kelling Sanatorium, the last model being constructed by a patient. Mention here should also be made of the models illustrating progressive overcrowding as a cause predisposing to consumption and its spread, which have been constructed by Mr. R. Sykes, R.I.B.A., and lent by Dr. John F. J. Sykes. The Huddersfield exhibit of models of back-to-back houses, old and new type, is also instructive.

An important development of the treatment of tuberculosis in sanatoriums is the graduated system of work for the patients, and many of the sanatoriums represented show photographs of the system adopted. Actual specimens of manufacture by the patients are also displayed. By the Victoria Home for Invalid Children, Margate, some specimens of wool garments are shown, while the St. Vincent's Cripples' Home show photographs of the inmates at work knitting, tailoring, and brush making. Specimens of brush work are exhibi[illegible] Home. From the Royal [illegible] at Craigleith come pictures the patients engaged in work of many kinds, domestic, industrial, and agricultural. The photographs and actual specimens of work done by the patients in the Blencathra Sanatorium, Threlkeld, form a most interesting and instructive exhibit, as do also the series of photographs shown by the Frimley Sanatorium. This latter institution includes in its exhibit spades and other implements graduated in weight and size in accordance with the strength of the patients using them. The work done at King Edward VII. Sanatorium at Midhurst is also shown photographically, and the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis at Benenden, the Inverness-shire Sanatorium, and the Daneswood Sanatorium for the Jewish Poor illustrate the work of the patients in similar ways. This feature of the exhibition is one which requires the earnest and attentive study of all who are in any way concerned in the management of sanatoriums. The exhibits are necessarily somewhat scattered about in different parts of the exhibition, but a special study of the subject can be easily made with the aid of the catalogue

A small room is set apart as a pathological section. Here are specimens of the liver, lung, and udder of the cow affected with tuberculous disease, lent by Dr. E. W. Hope from the public health department of Liverpool. Similar specimens, together with illustrations of infected and dirty milk, are lent by Professor S. Delépine from the Manchester University, while Professor G. Sims Woodhead shows a large number of bottle specimens from the Humphry Museum of the University of Cambridge. These are mostly from the human subject. The Royal College of Surgeons of England also lends some pathological specimens both of the human subject and of birds. X ray photographs are also lent by the Humphry Museum and by the Royal Chest Hospital, while others are provided by the Local Government Board and Dr. E. J. Steegmann, and lantern slides are sent by Dr. Arthur Ransome.

It is intended to open similar exhibitions in all the poorer districts of London in turn, and later an extended tour of the provincial cities and towns will be made. It is also hoped that the work may be supplemented by smaller portable exhibitions in travelling vans, so that the propaganda may reach the country districts. The movement is entirely free from commercial enterprise and no charge will anywhere be made for admission.

Looking Back.

FROM

THE LANCET, SATURDAY, June 11th, 1831.

MEDICINAL PROPERTIES OF THE SULPHURET OF CARBON.

The sulphuret of carbon, though discovered by Lampadius in 1796, has not yet been introduced into the medical dispensatories. MM. Wutzer and Pellengham have lately investigated its properties with the following results:—

1. The sulphuret of carbon is one of the most powerful of the diffusible stimulants yet discovered.
2. It excites powerfully the activity of the heart and arterial system.
3. Its internal use quickly determines acceleration of the pulse, increased heat, and sanguineous congestion towards the skin, and genito urinary apparatus.
4. The most remarkable secondary symptoms are, abundant diaphoresis, increase of the urinary secretion and of the menstrual discharge.
5. It has been used with the utmost success as a remedy in chronic rheumatism, and in gout where no fever simultaneously exists.
6. The dose in which it is fit to give it internally, is from three to eight drops, in any convenient liquid vehicle, or on

---

[2] THE LANCET, vol. ii., 1908, p. 132.

a bit of sugar. It is also very useful as a liniment, which may be formed with sulphuret of carbon ℥ij, and camphorated alcohol ℥iv; olive oil may perhaps be advantageously substituted for the camphor solution.—*Journal de Chimie.*

[The sulphuret of carbon is easily prepared by passing the vapour of sulphur over charcoal heated to redness, in a porcelain tube; it is a transparent, colourless liquid, of great levity, and producing intense cold by its evaporation. From the extreme cheapness at which it may be prepared, we are disposed to regard it as a valuable addition to our remedial agents.]

PRICE OF SUBJECTS IN PARIS.

To the Editor of THE LANCET.

SIR,—I observed in the last Number of your Journal an article on "medical education," to which was appended a note, stating the price of subjects to be in Paris about ten shillings. I beg to inform you that for the last three years I have resided in Paris, and have had an opportunity of knowing the price of subjects, and I assure you that five francs, or four shillings and twopence, is the uniform price for unopened subjects, and three francs, or two shillings and sixpence, for opened ones.

I am, Sir, respectfully yours,

23, Castle Street, June 1. JOHN FORDE.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7115 births and 3893 deaths were registered during the week ending June 5th. The annual rate of mortality in these towns, which had been equal to 14·7 and 13·9 per 1000 in the two preceding weeks, further declined to 12·3 in the week under notice, and was considerably lower than in any previous week of this year. During the first nine weeks of the current quarter the death-rate in these towns averaged 14·8 per 1000; the rate in London during the same period did not exceed 14·3. The lowest recorded annual death-rates in these towns last week were 3·1 in East Ham, 4·0 in Leyton, 5·1 in Wallasay, and 5·9 in Handsworth; the rates in the other towns ranged upwards, however, to 19·1 in Stockport, 19·4 in Wolverhampton, 20·1 in Wigan, and 24·0 in Merthyr Tydfil. In London the recorded death-rate last week did not exceed 11·6 per 1000. The 3893 deaths from all causes in the 76 towns last week showed a further decline of 483 from the numbers returned in the two preceding weeks, and included 359 which were referred to the principal epidemic diseases, against 413 and 417 in the two previous weeks; of these 359 deaths, 140 resulted from measles, 75 from whooping-cough, 55 from diarrhœa, 45 from scarlet fever, 33 from diphtheria, and 11 from "fever" (principally enteric), but not one from small-pox. The 359 deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·3 in each of the two preceding weeks. No death from any of these epidemic diseases was registered last week in Croydon, Sunderland, Southampton, Halifax, or in 14 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·4 in Norwich, 3·5 in Wigan, 5·0 in Wolverhampton, and 5·6 in Tynemouth. The fatal cases of measles in the 76 towns, which had been 168 and 178 in the two preceding weeks, declined again last week to 140, and were fewer than in any previous week of this year; they caused, however, annual death-rates ranging upwards to 2·2 in Salford, 2·3 in Bootle, 3·4 in Norwich, and 4·0 in Wolverhampton. The 75 deaths from whooping-cough also showed a considerable decline from the numbers returned in recent weeks; the highest death-rates last week from this disease were 1·6 in St. Helens, 2·0 in Great Yarmouth, and 2·8 in Tynemouth. The 55 deaths attributed to diarrhœa showed a slight further increase on recent weekly numbers, and caused an annual rate equal to 2·1 in Walsall. The 45 fatal cases of scarlet fever also showed an increase, and caused the highest proportional mortality in Burnley and in Tynemouth. Of the 33 deaths from diphtheria, 10 occurred in London and its suburban districts, three in Portsmouth, four in Manchester, and three in Leeds. The 11 deaths referred to "fever" showed a considerable further decline from the numbers in the three preceding weeks. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2173, 2234, and 2254 at the end of the three preceding weeks, had declined again to 2223 on Saturday last; 275 new cases of this disease [illegible] hospitals during last week, against 3[illegible] previous weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 214 and 225 in the two preceding weeks, declined to 172 in the week under notice and were 21 below the corrected average number in the corresponding week of the five years 1904–08. The deaths in London referred directly to influenza, which had been 20, 19, and 17 in the three preceding weeks, further declined last week to 10. The causes of 24, or 0·6 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during the week were again duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, Salford, and in 53 other smaller towns; the 24 uncertified causes of death included five in Liverpool, five in Birmingham, and two both in Warrington and in Coventry.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 989 births and 582 deaths were registered in the week ending June 5th. The annual rate of mortality in these towns, which had been equal to 17·5 and 16·7 in the two preceding weeks, further declined to 16·3 in the week under notice. During the first nine weeks of the current quarter the death-rate in these Scotch towns averaged 16·9 per 1000, while in the 76 large English towns the mean death-rate during the same period did not exceed 14·8. The death-rates last week in these Scotch towns ranged from 12·3 and 14·0 in Greenock and Leith to 19·4 in Dundee, and 19·8 in Perth. The 582 deaths from all causes in the eight towns showed a further decline of 14 from the numbers returned in the two previous weeks, and included 59 which were referred to the principal epidemic diseases, against 76 and 68 in the two preceding weeks. These 59 deaths were equal to an annual rate of 1·7 per 1000, against 2·1 and 1·9 in the two previous weeks; the mean death-rate last week from these principal epidemic diseases in the 76 large English towns did not exceed 1·1 per 1000. Of the 59 deaths from these epidemic diseases last week in the Scotch towns, 25 resulted from whooping-cough, 15 from diarrhœa, seven from diphtheria, five from "fever," five from scarlet fever, and two from measles, but not one from small-pox. The fatal cases of whooping-cough in the eight towns, which had been 38 and 40 in the two preceding weeks, declined last week to 25, of which 13 occurred in Glasgow, nine in Edinburgh, and two in Greenock. The 15 deaths attributed to diarrhœa differed but slightly from the numbers in recent weeks, and included five in Glasgow, four in Dundee, and three both in Edinburgh and in Aberdeen. Of the seven deaths referred to diphtheria, showing a slight increase, five were recorded in Glasgow, and two in Dundee. Of the five fatal cases of "fever," four occurred in Glasgow and one in Greenock; three were certified as cerebro-spinal meningitis and two as enteric. Of the five deaths from scarlet fever, three were returned in Glasgow and two in Edinburgh. The two fatal cases of measles were fewer than in any recent week; they included one each in Aberdeen and Paisley. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 109 and 94 in the two previous weeks, were 93 last week, and exceeded the number in the corresponding week of last year by 18. The deaths from violence in the eight towns were 14, of which nine occurred in Edinburgh and three in Glasgow. The causes of 17, or 3·0 per cent., of the deaths in the eight towns last week were unspecified or uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been

22·3 and 21·7 per 1000 in the two preceding weeks, further declined to 18·2 in the week ending June 5th. During the first nine weeks of the current quarter the death-rate in the city averaged 22·1 per 1000, whereas the mean rate during the same period did not exceed 14·3 in London and 16·7 in Edinburgh. The 139 deaths of Dublin residents from all causes during last week showed a further decline of 27 from the numbers returned in the two preceding weeks, and included 11 which were referred to the principal epidemic diseases, against nine and 13 in the two preceding weeks. These 11 deaths were equal to an annual rate of 1·4 per 1000, the death-rate from these epidemic diseases in the same week being only 1·3 in London, but was 2·1 in Edinburgh. Of the 11 deaths from these epidemic diseases in Dublin last week, four resulted from whooping-cough, three from "fever," two from measles, and one each from scarlet fever and diarrhœa, but not one either from diphtheria or small-pox. The 139 deaths in the city last week included 17 of infants under one year of age and 44 of persons aged upwards of 60 years; the deaths of infants showed a considerable decline and were fewer than in any previous week of this year. Five inquest cases and three deaths from violence were registered last week, and 52, or 37·4 per cent., of the deaths occurred in public institutions. The causes of three, or 2·2 per cent. of the 139 deaths registered in Dublin last week were not certified either by a registered medical practitioner or by a coroner; all the causes of the 1072 deaths registered in London last week were duly certified, whereas in Edinburgh the proportion of uncertified causes of death was equal to 4·2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: A. C. Bean to the *President*, additional, for temporary service at Medical Department, and E. D. J. O'Malley to the *Boadicea* on commissioning.

ROYAL ARMY MEDICAL CORPS.

Captain James M. Buist is placed temporarily on the half-pay list on account of ill-health (dated June 4th, 1909).

INDIAN MEDICAL SERVICE.

Lieutenant J. A. S. Phillips has been appointed to the medical charge of the 106th Hazara Pioneers. Captain H. O. Buckley has been appointed to the medical charge of the 31st Lancers.

TERRITORIAL FORCE.

Royal Army Medical Corps.

The arrangements for the training at military hospitals of the matrons on the rolls of Territorial general hospitals have been approved by the Army Council. Each hospital is allowed two matrons. The hospitals appointed for the training are the Royal Victoria Hospital, Netley; Queen Alexandra Military Hospital, Millbank; Cambridge Hospital, Aldershot; Connaught Hospital, Aldershot; Military Hospital, Devonport; Royal Herbert Hospital, Woolwich; Alexandra Hospital, Cosham; and Military Hospital, Colchester. It is proposed that the training time shall be from June to October in each year. General officers commanding-in-chief have been directed to send to the War Office as early as possible the names of matrons who can give attendance for training in the present season.

South Wales Mounted Brigade Field Ambulance: Captain John R. I. Raywood to be Major (dated Feb. 25th, 1909).

2nd Home Counties Field Ambulance: George Thomas [illegible]

[illegible] nbe to [illegible]

[illegible] Arthur John Martin to be [illegible]

[illegible] eutenant-Colonel Joseph Griffiths to be Colonel (dated May 6th, 1908).

For Attachment to Units other than Medical Units.—[illegible]

Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Robert Ross Brown, from the 1st Kent Royal Garrison Artillery [illegible] ant-Colonel with the [illegible] h precedence as in the [illegible] Surgeon-Lieutenant- [illegible] Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). Supernumerary Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel William Dakin Waterhouse, from the 4th Volunteer Battalion, The Royal Fusiliers (City of London Regiment), to be Lieutenant-Colonel, with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). [illegible] ary Surgeon-Colonel [illegible] Volunteer Battalion, [illegible] to be Lieutenant-Colonel, with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Captain Arthur Conning Hartley, from the 1st Bedfordshire Royal Engineers (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). [illegible] 1908). Captain Richard Emmett to be Major (dated Oct. 23rd, 1908). Captain Alan Y. Greenwood resigns his commission (dated March 22nd, 1909).

Attached to Units other than Medical Units.—Lieutenant-Colonel and Honorary Surgeon-Colonel James K. Anderson relinquishes his commission, under the conditions of paragraph 59, Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform (dated March 3rd, 1909). Owen John Parry-Edwards to be Lieutenant (dated April 15th, 1909). Lieutenant-Colonel Arthur D. Webster resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated April 20th, 1909). Surgeon-Captain James Herbert Dixon, from the Welsh Divisional Engineers, to be Captain (dated May 6th, 1908).

THE JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the June issue of this journal Captain R. Tilbury Brown, R.A.M.C., continues his practical article "Hints on Camping Arrangements for Sanitary Officers," which has been written with a view of giving to medical officers of the Territorial Force useful hints on camp sanitation. The first part of the communication, which was published by our contemporary last month, dealt with the selection of the camp site, water-supply, latrines, and so forth, while the current contribution deals with the arrangements to be made before the arrival of troops, the general organisation of the camp, and the duties of the sanitary squad. The article is to be continued. Some notes written by Major E. T. F. Birrell, R.A.M.C., in appreciation of the organisation of the army, with special regard to the removal of sick and wounded from field medical units to the lines of communication, is mainly composed from official sources and affords interesting reading, as does also the "Australian Army Medical Corps," written by Major S. F. Clark, R.A.M.C. Major J. C. Morgan, R.A.M.C., and Captain D. Harvey, R.A.M.C., jointly contribute an important paper on an Experimental Research on the Viability of the Bacillus Typhosus as excreted under Natural Conditions by the "Chronic Carrier," and Major S. L. Cummins, R.A.M.C., deals with surface vaccination in suspected cases of tubercle. Among the clinical notes is one on a diphtheroid bacillus isolated from water, which the author, Major J. G. McNaught, R.A.M.C., states has not been tested for pathogenicity; and there is an account of the Zittman treatment of syphilis at Netley by Major D. Lawson, R.A.M.C. This treatment, in spite of the great discomforts attending it, seems to be popular among the men. Many medical officers, the author states, who have had charge of this treatment, believe that in the case of men invalided from India who have been a very long time on mercury, and have accumulated a very large quantity in the tissues, the course benefits by assisting them to excrete the drug.

THE RED CROSS SOCIETY AND THE TERRITORIAL SCHEME.

Mrs. C. Davies Gilbert, vice-president of the district branch of the British Red Cross Society, Eastbourne, on

June 3rd gave an "At Home" at Manor House, Eastbourne, at which Sir Frederick Treves was present. In a brief speech Sir Frederick Treves said that an extensive movement, which was not yet completely developed, was proposed for the Territorial Army. The War Office was about to issue a memorandum of what it hoped the Red Cross Society would do under the Territorial scheme in case of need.

Correspondence.

"Audi alteram partem."

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—The profession is indebted to you for your judicious editorial comments on this difficult question and for the opportunities you have afforded us to discuss its many bearings in your correspondence columns. There seems reason to believe, thanks largely to your efforts, that all interested in this subject may be brought to agree that from a strictly professional point of view the proposal of the County Council to make use of voluntary charities to secure treatment for their scholars should be strenuously resisted by medical practitioners. No schemes for applying the County Council's subsidy to provide honoraria for senior students or clinical assistants or to pay a nominal rental for unoccupied out-patient departments can conceal the fact that this proposal cuts at the root of what should be a fundamental professional principle—viz., that unpaid professional service should not be given to institutions which are supported or aided by grants from the rates or the exchequer. This is a principle which applies, not only to medicine, but to all other professions and occupations by which men or women earn their living and is one which needs to be constantly remembered in these days of increasing state and municipal activity.

Unfortunately, it is not enough for the profession to recognise the danger of acceding to this proposal of the County Council in order to ensure that it will not be adopted. There is reason to suppose that at some hospitals the governors may take up the position that this is a matter in which they are not bound to be guided by medical opinion. That the profession is not sufficiently united to make its wishes prevail in such circumstances is a matter for profound regret; but may we not hope that such a condition will before long be remedied? In the meanwhile it seems desirable that we should be able to point out to our lay governors that there are reasons altogether outside this professional principle which make it desirable to refuse the County Council's proposal.

There are two features of this proposal which are a serious menace to the great system of voluntary hospitals, of which the majority of Britons are justifiably proud. There is, first, the acceptance of money from a body representing the whole community and able to compel contributions to its funds; and, secondly, the entrusting to the same lay authority the responsibility of selecting cases for medical treatment. It should not be difficult to persuade the governors of hospitals that to accept money from the rates or the exchequer will very shortly render their hard financial task still harder. Many of these have been interested in voluntary schools and will remember the chief cause of the intolerable strain of supporting these institutions. It is of the essence of charitable effort that it should be actuated by a greater sympathy or by a greater foresight than that possessed by the community at large. So soon, therefore, as the philanthropist finds that his example is about to be followed by the community, as represented by the County Council or Parliament, he ceases to subscribe and finds some other charitable object in which he may hope again to lead public opinion. The knowledge that a definite grant is made annually by the County Council to a voluntary hospital, even though it be for a restricted part of its work, will, if precedent be followed, speedily lead to a loss of voluntary subscriptions and legacies of far greater value than the subsidy. The other dangerous feature of the County Council's proposal is not so easy to bring home to those who are interested in the voluntary hospitals, whether as governors or medical staff. Nevertheless, it is of vital importance and must be kept well in mind in handling this question as well as in dealing with the important changes in hospital administration that will come when the Poor-law medical service is reformed. If our great voluntary hospitals are to survive the awakening of the public conscience as to medical matters which the activity of the County Council and the Poor-law Commission's report indicate, it can only be by their impressing on the philanthropic public that they will still be able to provide for the public something altogether different from the medical service provided by the municipality or the State, or whatever body it may be which will take the place of the "broken-up" Poor-law.

It is true that in the past the voluntary hospitals, shocked by the inefficient medical service supplied by the State, have supplemented its deficiencies and provided the simplest medical treatment for all-comers. Already this has become almost unnecessary, and in the future voluntary hospitals must base their appeal for support on the grounds that their service is not parochial but is Empire-wide, and consists essentially in dealing with obscure and difficult cases and in the making of medical knowledge and its diffusion throughout the world. To establish and consolidate this position is the duty of everyone who believes that voluntary hospitals are worth maintaining. No more serious blow could be dealt to the unique reputation of these institutions than for our governors to contract with the County Council for the wholesale treatment of ailments which are said to afflict 5 per cent. of the children attending the schools. Let the County Council make whatever arrangements it sees fit with medical practitioners to treat these patients in the immediate neighbourhood of the child's home or school, and let the medical man entrusted with this duty recommend the help of the hospitals in those cases which are found on full investigation to require special facilities for diagnosis or treatment.

I am, Sir, yours faithfully,
June 6th, 1909. LAURISTON E. SHAW.

FRACTURE OF THE SCAPHOID BONE OF THE WRIST.

To the Editor of THE LANCET.

SIR,—You invite your readers to record any cases similar to that reported by M. Judet. I can recall several such. One was that of a boy, aged 15 years, who fractured his scaphoid in turning a hand somersault. When seen some seven weeks after the accident he possessed but little movement at the wrist, while any attempt at extension was very painful. Pressure over the bone even at this date was resented and there was considerable pain at night over the outer and palmar aspect of the hand. The x ray showed a transverse fracture through the centre of the bone, with dorsal displacement of the inner half. I have not met with any old case which did not exhibit limitation of movement most marked in the direction of flexion.

Fracture of the scaphoid is easily the most common of the carpal bones. It occurs with rare exceptions from a fall on the extended hand. The most obvious clinical sign is an acute pain when the wrist is forcibly adducted and extended. In addition one finds a swelling over the radial wrist on the dorsal aspect, a general rigidity and, as Codman and Chase have pointed out, an acute tenderness in the anatomic snuff-box when the hand is adducted. In some cases I have noted a painful area covering the palmar aspect of the thumb and index finger. I have detected crepitus in one case only.

In a recent case I would recommend the surgeon to put forcible pressure over the scaphoid while the wrist is flexed and adducted. This is best done through the snuff-box between the first and second extensors of the thumb. The wrist should in any case be kept fixed in the well-extended posture for at least a fortnight. During this hyper-extension the fingers should be left so that they may be voluntarily freely moved. For two weeks more massage and movement should be alternated with fixed hyper-extension and then treatment may end. I am convinced that immediate mobilisation and massage is a grave error. In old cases forcible wrenching under anæsthesia and fixation in hyper-extension offers the best mechanical advantage to wrist and fingers. In two instances I have excised the prominent fragment with relief as regards pain but with no increase of mobility. I am, Sir, yours faithfully,

Liverpool, June 8th, 1909. ROBERT JONES.

MICROCOCCUS TETRAGENUS AS A PATHOGENIC ORGANISM.

To the Editor of THE LANCET.

SIR,—In the Proceedings of the Royal Society of Medicine (Clinical Section) for April, 1909, Dr. E. von Ofenheim contributed a paper on the Vaccine Therapy of *Septicæmia*, in the course of which he commented on the scarcity of the literature concerning micrococcus tetragenus infections. It accordingly seems worth while to place on record my experience of that organism. In 1901–1902 I was serving in H.M.S. *Galatea* in home waters, and from the suppurations (boils, &c.) which occurred recovered what organisms I could. In that ship I only once found a gelatin-liquefying coccus (staphylococcus); I never found a streptococcus, but from all the cultures worked out I obtained what was, I have no doubt, micrococcus tetragenus. I recognised it in smears of sputa as well in that ship. I also found, once only, a pathogenic yeast growing in a venereal sore. I have never found M. tetragenus in other ships. M. tetragenus seemed to me to be associated with little pus formation, but to excite large phlegmons (extensive surrounding swelling and redness) and to cause much, sometimes profuse, serous discharge.

Dr. von Ofenheim speaks of a septicæmia in rats and mice caused by this organism. I do not think we had any mice in the ship, and rats must have been few, as I have no remembrance of them. In those days we did no blood cultures, and I am sorry to have no further information. Still, it is a matter of some interest that the same observer should have found micrococcus tetragenus frequently associated with the suppurations of one ship, yet never in those of another, both these ships being in English waters.

I am, Sir, yours faithfully,
W. E. HOME,
H.M.S. *Daedalus*, Bristol, May 30th, 1909. Fleet Surgeon, R.N.

THE AFTER-TREATMENT OF CATARACT EXTRACTION.

To the Editor of THE LANCET.

SIR,—I have read Mr. A. Lawson's lecture in THE LANCET of May 29th on the after-treatment of cataract extraction with particular interest, because for the last 15 years I have adopted a different method which, I think, makes the patient more comfortable both in body and mind. So far no bad results have occurred which could reasonably be traced to the freedom my patients enjoy, and the number of extractions (about 700) is sufficient to have disclosed any serious dangers attaching to my plan.

After the operation the eye is covered with a small piece of cotton-wool, fitted carefully into the inner corner by the nose, and this is kept in place by a piece of fine isinglass plaster. The plaster is pulled just tight enough to exert a little pressure over the inner corner of the eye, but no pressure is made on the globe; a very slight pressure in the corner will keep the lids closed. Over the wool, but not pressing on it, is placed a conical shield of Willesden roofing paper, and this is fixed in position with short strips of isinglass plaster, one over the bridge of the nose and the others on the cheek and forehead. The unoperated eye is never covered, nor are the hands tied; the shield will resist a hard blow, and the eye is never accidentally injured under it. A shield stuck on in this way is much more comfortable than any bandage round the head.

I do the operation in the morning and make the patient go to bed and keep very still all day, and the next morning, unless there is some special reason against it, which is very seldom the case, he gets up and sits in a chair, keeping fairly quiet. On the morning after the operation the shield is taken off, the wool changed, and a drop of atropine and cocaine applied; subsequently the eye is dressed each morning, but the atropine is not used oftener than is necessary to keep up the dilatation of the pupil. In the summer the patients are often out in the garden on the third or fourth day after the operation and derive much benefit from it; they eat their ordinary food and, in fact, are not treated as sick people at all.

I never tell a patient to expect pain, but tell him that if he should chance to get any after the operation he need not be alarmed at it. A large number say they have no pain. I believe pain may be caused by pressure on the eye and by the heat of a thick dressing, and am therefore careful to use only a little wool and to apply what little pressure is necessary to keep the eye shut only in the corner. An empty anterior chamber is not necessarily a cause of pain, for it may be empty for days together without any pain at all. At one time I bandaged both eyes and kept the patients in bed, but gradually gave up such irksome details as seemed to be possibly unnecessary and, if so, harmful, and have thus arrived at my present plan.

There is nothing worse for old people than thoroughly to upset their accustomed way of life, and, by making "heavy weather" of their treatment, give them the idea that they are undergoing some dangerous process. Of course, anxiety is inseparable from surgery, but the surgeon should keep it to himself, and the more light-hearted the patient can be kept the better will he recover and the less will his pain hurt him. To blindfold a patient, handcuff him, feed him on slops, tell him to lie still in bed and keep his mouth open if he moves, and to expect pain—all this seems to me the best way to ensure that he shall be nervous and have pain; and if to this suggestive treatment is added a dose of chloral there is surely enough to account for the night terrors and dementia Mr. Lawson describes without the shock of the little operation. If all this treatment were necessary for the safety of the eye it would have to be endured, even though it is obviously bad for the patient. My experience convinces me that it is not necessary, and that patients may get through the operation for cataract without any material discomfort. I am, Sir, yours faithfully,

J. F. BULLAR, M.B. Cantab.,
Southampton, June 1st, 1909. F.R.C.S. Eng.

THE EMMANUEL MOVEMENT AND THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—We are constantly in receipt of letters from your side of the Atlantic which show that there is a widespread misunderstanding among physicians, clergymen, and others as to the principles and methods of what has come to be known as the "Emmanuel Movement." As those who are responsible for the inauguration and general guidance of this work, we feel it to be our duty to correct this misconception, and to acquaint the British public with the real aims and motives of our undertaking. We ask you, therefore, to be good enough to publish the following statement:—

The fundamental purpose of the Emmanuel Movement is to ally in friendly coöperation the doctor of medicine, the psychologically qualified minister of religion, and the trained social worker with a view to the alleviation and arrest of those semi-nervous, semi-moral disorders which go by the name of "functional disorders of the nervous system." Hence, our aim is not to found or propagate a healing cult, or to practise medicine, or to substitute our activities for those of the physician. We could not do any of these things and at the same time retain our self-respect. On the contrary, our aim is to assist the physician in those cases where a moral or spiritual problem is involved. From the very beginning we have associated ourselves with reputable medical men, and without the general coöperation of the medical profession our enterprise would come to an end. The whole work is under rigid medical control, as will be seen from the following rules which we have adopted: (1) No person shall be received for treatment unless with the approval of and having been thoroughly examined by his family physician, whose report of the examination shall be filed with the church clinic records; (2) no patient shall be referred for diagnosis or treatment to any specialist or assistant save with the advice and consent of the patient's own physician; (3) all patients who are not under the care of a physician must choose one, and be themselves in his care before they can receive treatment at Emmanuel Church. It thus rests wholly with the physicians and not with the clergymen to decide whether a patient should be referred to a neurologist or other specialist, and which cases, if any, are suitable for treatment by moral and religious re-education. In view of these facts, we must decline to be held responsible for the action of any individual or organisation acting in contravention of any of these principles or methods. In England the committee which represents our work bears the title "Church and Medical Union."

We are, Sir, yours faithfully,
ELWOOD WORCESTER.
SAMUEL MCCOMB.

Emmanuel Church, Boston, U.S.A., May 24th, 1909.

CASE OF CEREBRAL HÆMORRHAGE FOLLOWED BY HYPERPYREXIA AND DEATH.

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 15th, 1909, p. 1386, Mr. Vincent P. Norman describes a case under the above heading, and adds, "a clinical fact not often recorded if we judge from a perusal of literature bearing on the subject."

The above remark, and my having had a similar case some time ago, must be my excuses for recording the following. The case occurred on board the R.M.S. *Oropesa*, of the Pacific Steam Navigation Company. The patient, a lady, aged 53 years, was very stout and of plethoric appearance. Her husband informed me that she had always been in fairly good health, and as a rule took but little alcohol. Soon after leaving Lisbon, however, I noticed that she took a good quantity of red wine with her meals, and as we got into tropical heat the quantity was considerably increased. On the third day after leaving St. Vincent, Cape de Verde Islands, I noticed that her face was very congested, and I feared apoplexy. About 4 A.M. the following morning I was hurriedly sent for to see the lady in question, the steward informing me that she had had a "fit." On my arrival I found the patient quite unconscious, pupils were dilated and inactive, radial pulse could not be counted, respiration was at first markedly stertorous, becoming later Cheyne-Stokes in character, and there was complete relaxation of her extremities. Her face was very cyanosed and she was obviously dying.

The point, however, that impressed me most was the sensation of extreme heat imparted to my hand. I had felt nothing like it before, and for this reason I decided to take her temperature. In the axilla the thermometer registered 107·8° F., and in the rectum 108·6° F. To make sure that the thermometer was accurate I obtained another one, which gave precisely the same result. The patient died within an hour of my seeing her, and was buried at sea the next day.

I am, Sir, yours faithfully,
MORGAN RICHARDS, M.D., B.S. Durh.

Chelsea, S.W., June 4th, 1909.

FERGUSSON *v.* MALVERN URBAN DISTRICT COUNCIL: APPEAL OF PLAINTIFF BEFORE HOUSE OF LORDS.

To the Editor of THE LANCET.

SIR,—Mr. F. W. Joshua writes under the above heading in your last issue "to prevent any misconception of the true state of facts that may arise from reading" my letter in your issue of May 29th. I cannot see that his letter is called for by anything I said in mine, nor can I see that it serves any useful purpose; but Mr Joshua probably differs from me on this point. On the contrary, I think that his letter, far from fulfilling its object, renders the case liable to be misunderstood, as anybody reading it, and not having followed the case closely, would naturally conclude that my father had stolen the water-supply. Such a conclusion is quite wrong, and is detrimental to the character of a medical man; and it is on this account that I now beg the hospitality of your columns to enable me to correct the inevitable misapprehension that must arise from a perusal of Mr. Joshua's letter.

The jury found that Dr. Fergusson had no right to the water, because he could produce no documentary or other evidence that he was entitled to it. There is unimpeachable evidence that the pipe conveying the water had been exactly as it was found as long as Dr. Fergusson had occupied the establishment, 16 years, and that no alteration whatever had been made to it by anyone with his knowledge or on his behalf. It was probably the original means of supply from the time when the house was built in 1843, a time when no public supply existed and when anybody was at liberty to take water wherever it was to be found. This explains the absence of evidence as to ownership; and the jury had no alternative to finding that my father had no legal right to it.

The idea that he was *fraudulently* using it is negatived by the fact that the jury found him not guilty of contributory negligence, as was alleged by the defendants. Some of the wild assumptions and ridiculous conjectures which the jury were asked to believe, *without evidence*, were of a damaging character, and included the idea of my father having stolen the water. Repetition of these assumptions in the House of Lords was promptly cut short by the Lords asking point-blank whether there was any evidence whatever in support of them; as the Lord Chancellor said, "We want facts, not theories."

I think I have said enough to justify the last paragraph of my letter in your issue of May 29th, and to correct the impression which must be left by Mr. Joshua's letter; my father has through no fault of his own lost his case, but has emerged with a clean character, in spite of much "mud-throwing," and on that account he deserves the sympathy of all, especially his professional brethren.

I am, Sir, yours faithfully,
J. N. F. FERGUSSON, M.B. Cantab.

Malvern Hydropathic Establishment, Great Malvern, June 9th, 1909.

A PLEA FOR THE USE OF ANTI-DIPHTHERITIC SERUM.

To the Editor of THE LANCET.

SIR,—In my letter published in THE LANCET of June 5th under the above heading the report of Case 1 should have read as follows:—

"I saw C. D. on Nov. 5th, 1906, at 9 A.M., with quinsy, soft palate very red and œdematous, with a patch of membrane on left tonsil. He had been using hot inhalations of Friar's balsam but could not swallow. At 10.30 A.M. I injected 4000 B.U. and at 10 P.M., when I again visited him, he could swallow easily; a swab was taken with negative results. *The next day he had a profuse scarlet fever rash.* The case ran an ordinary course, but the quinsy aborted." In my communication the words which I have italicised were inadvertently omitted, and as they form the central feature of the case I trust you will allow me space to correct the slip.

I am, Sir, yours faithfully,
FRANK ARGLES.

Wanstead, N.E., June 5th, 1909.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

THE German Congress of Internal Medicine was held at Wiesbaden from April 19th to 22nd, Professor SCHULTZE (Bonn) being in the chair.

Diseases of the Stomach.

Professor LENHARTZ (Hamburg) presented a report on the results obtained by his method in the treatment of gastric ulcer. I may here mention that copious details of the method were contributed by Dr. J. Victor Haberman of Hamburg to THE LANCET of July 7th, 1906, p. 25. Professor Lenhartz said that the special features of his system included absolute rest in bed for at least four weeks and the wearing of an ice-bag over the stomach. Instead of the usual starvation diet the patient, even when hæmatemesis has occurred, received on the first day iced milk and four beaten-up eggs, sometimes with a little wine. The daily quantity of food was gradually increased, so that on the seventh day the patient began to take eight eggs, 40 grammes of sugar, 800 grammes of milk, 70 grammes of chopped raw meat, and 100 grammes of milk and rice;

while on the fourteenth day he began to take eight eggs, 50 grammes of sugar, 1000 grammes of milk, 70 grammes of chopped raw meat, 200 grammes of milk and rice, 100 grammes of zwieback (a kind of rusk or "pulled bread"), 50 grammes of raw ham, and 40 grammes of butter. Professor Lenhartz pointed out that the starvation diet formerly in use was very detrimental, especially to anæmic patients, and that the egg albumin answered well for fixing the free hydrochloric acid in the stomach. There had now been 295 cases treated by this method—262 of them immediately after severe hæmorrhage. Of these cases only seven—i.e., 2·3 per cent.—terminated in death. In only 18 cases did fresh hæmorrhage occur. Ne[illegible] given, as it was essential [illegible] The death-rate was muc[illegible] under any other, Dr. Leube's method included. The patients [illegible]ital until no blood had been [illegible] weeks. When hæmorrhage [illegible] must be suspected to be one of either cancer or cirrhosis of the liver.

Dr. ROSENFELD (Breslau) said that the aim of treatment in all diseases of the stomach was to prevent occlusion of the pylorus. *This was done by the administration of fat in the* form of cream. The other food must be prescribed according as free hydrochloric acid was present or absent; in acidity of the stomach albuminates must be given and carbohydrates avoided; in hypo-acidity of the stomach it was advisable to give albuminates sparingly and carbohydrates freely. The meals should be taken at intervals of six hours, so as to allow the stomach sufficient repose. Previously to the above diet, for four days the food should consist of nothing but cream in a quantity of 500 grammes three or four times a day. This diet had a styptic effect in hæmorrhage of the stomach, it opened the pylorus, and decreased the hyperacidity.

In the discussion, Professor von LEUBE (Würzburg) stated that among 627 cases of gastric ulcer treated by him during the past 11 years the mortality was 0·3 per cent.; in cases attended with hæmorrhage it was 2·5 per cent. He pointed out that the four principles aimed at in his treatment were absolute rest *for a fortnight, small doses of Carlsbad* salts, hot poulticing, and starvation diet. He was in favour of abstinence from food, because vomiting was often produced even by small quantities. In hæmorrhage lasting for two or three days total abstention from food was advisable. The administration of morphine was useful for checking peristalsis and adrenalin for checking hæmorrhage. He agreed with Professor Lenhartz that purgatives should be avoided.

[illegible] attention to the fact [illegible] were evident points of [illegible] of north and south *Germany respectively, and that owing to these differences* there might be diversities of opinion on questions relating to diet. In north Germany hyperacidity was rare.

Dr. GERHARD (Basle) gave comparative statistics of the Leube and Lenhartz procedures. He said that patients treated by Leube's system could leave their beds on an average after 19·4 days and could leave the hospital on an average after 39·6 days; the corresponding figures under the Lenhartz system were 25·1 and 40·3 days.

Professor SCHMIDT (Halle) said that rest in bed was more important than the diet; by the *horizontal position* of the body in bed the stomach became able to move its contents.

Dr. VON TABORA (Stra[illegible]es of atropine for the purpose [illegible] Of 100 patients treated acc[illegible] had after a *fortnight only a little decreased in weight,* while 42 had even increased.

The Action of Digitalis on the Organs of Circulation.

Dr. OTFRIED MULLER (Tübingen) said that intravenous injections of digalen and strophanthin in the usual doses did not produce an obvious effect on the vessels. Under the use of digitaline the force of the cardiac contractions was only slightly increased in healthy persons, but it was strongly increased in cases of weakened heart. Digitalis and its compounds were cardiac tonics, whilst carboni[illegible] acted on the vaso-motor system.

Dr. FLEISCHMANN (Berlin) recommended [illegible] strophanthin for intravenous injections instead [illegible] In patients suffering from cardiac [illegible] ften striking, the pulse becoming [illegible] cyanosis disappeared.

Dr. VOLHARD (Mannheim) recommended that in disorders *of the circulation adrenalin should be injected in doses* varying from 0·5 to 1·0 milligramme. The effect of this was that cyanotic patients acquired a pale complexion, the blood pressure increased, and a general improvement manifested itself.

Professor KRAUS (Berlin) said that he approved of the administration of adrenalin in syncope, and he had even given six injections daily without any ill-effect. Used in this way adrenalin was always satisfactory and it had evidently a tonic action on the heart.

Professor HEUBNER (Berlin) said that he had given in 12 *hours to children suffering from septic diphtheria as much as* 12 cubic centimetres of a solution of adrenalin of strength 1 per 1000.

Peripheral Sensibility.

Dr. HENRY HEAD (London) read a paper on Peripheral Sensibility and its Estimation. In his opinion the afferent nerves were of three kinds, respectively conveying impulses which were sorted in the central nervous system into the three great functional groups of (*a*) touch, (*b*) pain, and (*c*) temperature and sense of position. Recovery of sensation after complete division of a peripheral nerve began with disappearance of the analgesia and with the return of sensibility to the extreme forms of temperature, but the area over which gentle touching could not be felt remained unaltered for a much longer period. The recovered sensibility to heat and cold was due to the presence of minute areas ("hot and cold spots"), each of which could be stimulated by heat or cold alone. This form of sensation was designated protopathic sensibility. At a later period it became possible to discriminate two points with more or less approximation to the normal accuracy. This form of sensibility was designated epicritic, since it was peculiarly *associated with the localisation and discrimination of* cutaneous stimuli. Every peripheral afferent nerve contained protopathic and epicritic fibres.

Dr. SCHÖNBORN (Heidelberg) said that he had made a trial of Dr. Head's methods in 60 cases of organic nervous disease and in his opinion they gave satisfactory results. For testing the rise of temperature he recommended Miescher's apparatus, which was preferable to the [illegible] which had nothing to do with a diminution of the cold points, but must be regarded as a protopathic feeling of discomfort. There was apparently a contradiction in Dr. Head's opinion that this protopathic zone was only observed in troubles of *the peripheral nerves, but it must be considered* that the disease was localised, not in the medulla, but in the region of the roots. Dissociation of disorders of peripheral sensibility was much more frequent than has hitherto been suggested and could be recognised only by the exact method of Dr. Head.

Professor GOLDSCHEIDER (Berlin) said that the existence of [illegible] nervous system seemed to [illegible] facts observed by Dr. He[illegible] of stimulation. Dr. Head's protopathic *state was, in his opinion,* identical with Professor Leyden's relative hyperæsthesia. The difference between deep and other sensibility was justified. Such differences as those between the protopathic and epicritic systems were seen when the nerves were compressed, and even when menthol was *applied* to the skin. Such relative hyperæsthesia was observ[illegible] not always justifiable *from* [illegible] of sensation to assume the [illegible] of fibres. Irradiation in the protopathic stage was caused by the cohesion of the nerve fibres in the central region. In the peripheral part of their course the elements were lying together; in the medulla they were separated, but a connexion was maintained by the ganglia. *This* was the cause [illegible] points had [illegible] the genesis [illegible] explained; it possibly depended on an [illegible] ensibility.

Dr. HEAD, in his reply, said that Professor Goldscheider's view with regard to the connexion of the fibres was not in

With comparatively dry air, the oftener it is changed in the shed the more necessary is it to have artificial humidity in aid of the weaving process. In 1902 the Haldane Committee recommended a standard of 12 volumes of CO_2 per 10,000, or 20 volumes when gas or oil is used for lighting. This proposal was much criticised, and by some considered reactionary, and so required careful consideration by the committee. *Authorities, such as Parkes, de Chaumont, and* Pettenkofer, recommended a standard of six to ten volumes per 10,000, and it has been generally accepted that the CO_2 was an indication of other impurities injurious to health rather than the CO_2 itself. This idea, however, seems now to be looked upon as "early Victorian." The trend of opinion now is to treat the idea of something injurious existing in expired air beyond the CO_2 itself, as a myth, and that far more CO_2 in the air can be breathed comfortably than is usually thought desirable provided that other conditions are favourable and that the supply be continuously changed. For instance, there is a mill in Blackburn where the same class of goods is manufactured in two sheds under the same roof but divided by a partition. In one shed there is artificial humidity while the other is "dry." In the latter the CO_2 varied between 34 and 41 volumes per 10,000 during many months, yet the workers were as healthy as those in the "wet" shed where the standard was maintained. No single complaint was made by the operatives in the dry shed where there is no legal standard, while in the humid shed complaints were universal.

The evidence of Dr. Haldane, Dr. Leonard Hill, Dr. M. S. Pembrey, and Dr. A. E. Boycott goes to show that the ill effects of crowded rooms are due less to the percentage of CO_2 than to other factors, as "the heat, humidity, and nervous fatigue from excessive illumination and excitement." They say:—"One cannot detect any bad effect from 60 volumes per 10,000 when the temperature of the room is low;" and "The important thing is to keep the wet bulb temperature low." "The quality of freshness and stuffiness in a building, and in consequence the energy or slackness of the inhabitants, has nothing to do with the content of the air in CO_2 as such. Cool air free from unpleasant smell but containing 3 per cent. of CO_2 "is found to be a distinctly invigorating mixture." These opinions are backed up by many quotations from European and American physiologists to the effect that, contrary to the old idea, "There is no poison in breath." "Whenever in shut-up, crowded rooms certain impairment of health ensues, involving headache, dizziness, sickness, &c., these symptoms are attributable solely to heat retention." "The normal conditions of the surrounding atmosphere, viz., temperature, humidity, and movement, are of enormously greater importance for our comfort and health than the chemical composition of the air. Further, the refreshing sensation noticeable on abundant ventilation of closed rooms or in the open air, results not from the greater chemical purity of the air, but from the more rapid heat-loss from the body." It is easy to understand that, influenced by these views, the committee feels justified in recommending that in humid sheds the standard of ventilation should be 12 volumes of CO_2 per 10,000, and that when gas or oil is used for illumination 20 volumes of CO_2 in 10,000 should be allowed.

As regards the maximum temperature of the wet-bulb thermometer the committee thinks that the evidence scarcely justifies it in coming to a final conclusion. Notwithstanding this, it unanimously expresses the opinion that the discomfort and possible injury of the operatives can best be met by fixing a maximum limit of wet-bulb temperature and by securing between the wet- and dry-bulb temperatures a difference sufficient to prevent the deposit of moisture. The use of steam for humidifying is generally condemned. [illegible] urators" which [illegible] of ventilation [illegible] truction of the sheds, by which the air-intake is in the roof, and so is heated by the outflowing air. It is urged that the whitewashing of the roofs should be more thoroughly done, and the steam-pipes should be kept better covered. It is also suggested that the taking of the body temperature, which was begun by Dr. E. L. Collis, H.M. medical inspector of factories, should be resumed, especially in sheds where the heat is abnormally high. They should be visited on the hottest days of the summer, so that some definite information as to the effects of working in damp atmospheres at high temperatures could be obtained. To carry this out it is suggested that the help of [illegible] be obtained, and if this [illegible] be hoped that this extr [illegible] pay. Steaming has, it seems, been largely superseded by appliances for introducing "atomised" water into the sheds, and frequently this is also used for the double purpose of *ventil*[illegible] *s the wet-bulb* [illegible] s very unpopul[illegible] Burnley, Nelson, and Colne the operatives have steadily refused to work in the sheds if artificial humidity is introduced, and no standard of ventilation has been fixed for them. The amount of CO_2 in these sheds in winter is, on the average, 16·5 volumes in 10,000, but exceptionally this is much exceeded, and legislation is desirable in these cases. Mechanical ventilation does not seem to be much used in the dry sheds, but it has been complained of as causing draughts, which would probably not have been the case if the incoming air had been warmed. The purity of the water used is, of course, important, and with the assistance of Mr. Scudder a standard of purity has been agreed on. Briefly, "any water which absorbs from acid solution of permanganate of potash in four hours at 60° more than 0·5 grain of oxygen per gallon of water shall be deemed to be liable to cause injury to the health of the persons employed." Cloak-rooms are recommended, but there are some difficulties met with. A self-registering hygrometer, to do away with the labour at present involved in taking records three times daily, is very desirable, but none so far are fitted to stand the dust and vibration of the weaving sheds.

Summarising the recommendations of the committee, a limit of the wet-bulb temperature should be fixed at which all admission of artificial humidity should cease, the limit to be determined by early experiment and to be the lowest necessary for efficient weaving. The schedule of humidity should be amended by eliminating all temperatures above the maximum, to be hereafter determined, and all temperatures below 50° on the dry bulb. The standard of ventilation in humid sheds should be altered from 9 to 12 volumes of CO_2 per 10,000. That in dry sheds 15 volumes of CO_2 in 10,000 should be the standard; that draughts must be avoided in the sheds; that a standard of purity should be fixed for water to be used for the purpose of humidifying; that there should be cloak-room arrangements; that the readings of the thermometer *should be taken jointly by representatives of* employers and employed; and that there should be a standard hygrometer. It is also recommended, among other details, that the size of steam pipes for the wet bulb should remain as at present pending f[illegible] be maintained efficie[illegible] walls should be bett[illegible] of roofs. No doubt [illegible] would greatly, *in many cases, improve the conditions of work.* In a lecture at the Manchester School of Technology given by Professor J. Radcliffe recently, he passed some criticism on the report of the committee, especially as to the raising of the CO_2 standard to 12 volumes per 10,000, which he considered was a step in the wrong direction "as the available quantity of air for each individual was very small, [illegible] nt of moisture present, [illegible] of the air from dust." [illegible] ry to health resulted from uncleanliness, deficient ventilation, and constant changes of temperature directly due to the carelessness, indifference, and ignorance of the work-people. He had had direct experience of this. He favoured the mechanical systems of ventilation over the ordinary provisions for ventilation, heating, and humidifying of large factories and workshops. The difficulties *generally arose from insufficient* capacity of the plant, or from bad management. He thought also that some treatment of the yarn might be devised which would give good results without the presence of excessive moisture. There will always be some points on which opinion may differ, as, for instance, the question of humidity, to which Professor Radcliffe thinks too much attention has been paid, but the great mass of the workers seem to think otherwise. *If the suggestions of the Com*mittee are carried out the comfort and health of the operatives will no doubt be increased, provided that they do their share in maintaining the improved conditions under which they would work.

THE CLEANSING OF CAIRO.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE ORIGIN AND DEVELOPMENT OF THE SCAVENGING DEPARTMENT.—THE WANT OF FUEL.—THE DESTRUCTOR.—ONLY ONE-SEVENTH OF THE REFUSE TREATED.—MOUNTAINS OF FILTH ACCUMULATE UNDER THE CITY WALLS.—FLIES AND DUST FROM FOUL DUSTHEAPS INVADE THE STREETS.

PREVIOUS to the British occupation the care of keeping the streets of Cairo clean was confided to contractors, who certainly devoted some attention to the European quarter, but the natives were left to their own devices. Consequently household refuse was thrown out on the nearest convenient spot. Some house holders employed Zibals. These men represent a characteristic Oriental institution. The ordinary visitor or tourist does not perhaps realise that one of the greatest of Egyptian difficulties is the want of fuel. Yet it suffices to travel on an Egyptian railway to observe that there are hardly any trees and no forests. There are picturesque clusters of palm trees, but these do not provide timber nor good fuel. Imported coal, on the other hand, costs £2 a ton at the least, and in a country where wages are sometimes as low as 5*d.* a day it is obvious that the mass of the people cannot afford to burn imported coal. Wood also has to be imported for building and industrial purposes, and is far too dear to be used as fuel. Consequently rubbish is the only cheap fuel available. The Zibals are the collectors of rubbish. Householders pay them a small sum to fetch and carry away vegetable and other household refuse which they sell as fuel, especially to the public baths, and in this way perform a service of the greatest social importance in the life of the Egyptian In the big furnaces of the bathing establishments this rubbish can be burnt, otherwise it is difficult to see how Turkish baths could be provided for the people. In no way does Egypt, and especially Cairo, compare more favourably with Europe, and especially with England, than in respect to its public baths. There are 59 hammams or public baths in Cairo, and 49 of them were extensively frequented at the time of my visit. These are not new institutions, like the baths and washhouses in England, but are contemporaneous with the growth of Cairo itself. To the sanitary reformer nothing has been more disheartening than the statistics published from time to time showing how poorly the public baths built in British towns are frequented. It is true that of late years a bathroom is built in most private houses of a certain rental, and frequently even in workmen's cottages; but this is quite a recent innovation and one that is not always appreciated by those for whom it is provided. Indeed, there are frequent stories of the bath in model cottages being covered over to serve as a bedstead above and a coal-box or a rabbit hutch below. In the East, on the contrary, it has been a long-established custom for the great mass of the people, the women and the children as well as the men, to frequent the hammam. This, however, would be impossible if some form of cheap fuel had not been forthcoming, and thus the questions of public baths and of the disposal of household refuse have been linked together. The natural process, therefore, in an oriental town is to burn some of the household refuse in the furnaces of the public baths. Scavenger dogs and, in Cairo, scavenger cats devour another part of it, and the rest is allowed to accumulate on any neighbouring waste ground. But when the population of Cairo largely increased, and so many Europeans came that a European quarter was created, some attempt was made by the employment of contractors to establish systematic scavenging.

Shortly after the British occupation, and following particularly on a severe outbreak of cholera, the matter of refuse disposal had to be considered seriously. The first person to be engaged on this work was Mr. A H. Hooker, F.I.C., F.C S., a pupil of the late Charles Heaton, lecturer on chemistry at Charing Cross Hospital. Here I may be allowed a personal word. To Charles Heaton I also am deeply indebted not only for my first lessons in hygiene, but for introducing me to this journal, where I helped him in his work as Special Sanitary Commissioner till ultimately he retired and I succeeded to his post. In such circumstances it will readily be understood the pleasure it afforded me not merely to find Mr. Hooker among the first to welcome my arrival at Cairo, but to learn that he had honoured the name of our common master by rendering eminent service to the cause of hygiene in Egypt. In 1883 Mr. Hooker had just terminated his work as secretary to the Cholera Commission under Sir Guyer Hunter and had served through the whole of the epidemic. He then addressed a lengthy report on the sanitation of Cairo and other towns to the Egyptian Government. In consequence Mr. Hooker, on the advice of Sir Evelyn Baring (now Lord Cromer) was appointed sanitary inspector for Lower Egypt. Late in 1884 Mr. Hooker was charged with the executive sanitation of Cairo and Alexandria, under the title of chief inspector of the whole sanitary services. His first act was to dismiss the contractors who were highly paid for doing very little. At the same time he submitted an estimate for the carrying on of a sanitary service which was approved by the Government. Having thus secured the means, he purchased carts, horses, mules, brooms, and many other necessary utensils, making these purchases personally. Then he organised on a military basis a small army of scavengers, appointing old soldiers as foremen or chiefs of gangs. The next step was to establish municipal workshops for the construction and repair of all the utensils, and municipal stables for the horses and mules. Machine brushes were introduced and all the watering service was taken over. Formerly there had been great carelessness in the measuring of the water purchased by the authorities from a private company to water the public streets. Mr. Hooker introduced a meter which automatically and accurately measured the amount of water used and thus realised a considerable economy. At Alexandria he established a similar service; indeed, at all the larger towns he imitated more or less fully what had been done at Cairo. The principle was to divide large towns into separate districts with their chiefs or controllers and a separate staff. To better maintain discipline and order the posts in the departments were reserved for the army, old soldiers being given the preference and having a right to enter the Municipal Service Corps. In 1890 the sanitary authorities took over surface sanitation—that is, scavenging—and the public works department became responsible for road-making. Shortly after this Mr. Hooker retired from the service, with the satisfaction of having accomplished a task of great public utility and beneficence.

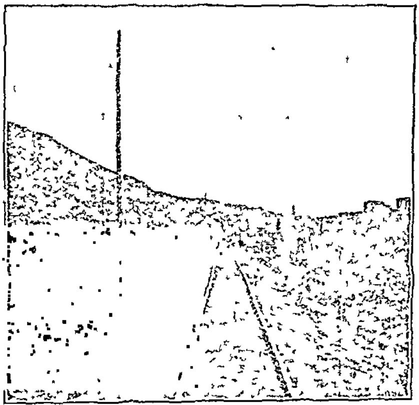
Mr. Felix E Powell is now responsible for the scavenging of Cairo. But circumstances have changed and are changing in the city and he very frankly recognises that the work in existing circumstances cannot be satisfactorily accomplished. When Mr. Hooker left the annual expenses of the service amounted to £16,000 per annum, now they amount to £47,372, and to do the work properly yet £13,000 more are needed, which is the same as saying that, if the figures may be accepted as a basis, at least a quarter of the necessary work must be left undone for want of means. Nevertheless, it is an inspiriting sight to visit the scavenging depot at Boulac. Here a fine international assembly of municipal machinery and appliances can be seen. There are English and German road-sweeping machines and thousands upon thousands of Italian hand birchwood brooms. The dryness of the climate causes the twigs to snap very soon and in the summer a broom will hardly last more than a week. It is quite a business merely to check these brooms, to hand out new ones, and to secure the old ones for the furnace at the destructor. At Cairo when asphalt or macadam is laid down in a street a small tax may be imposed in exchange and this covers the cost of keeping the street clean. But for the other streets which have only the bare earth no such revenue can be raised. Nor for the moment will any effort be made to pave these streets, for it has been decided to postpone all such expenditure till after the sewers are laid Therefore, there is no credit open—i e., no funds available—for sweeping unpaved streets, but under the Public Health Department there is a credit for prophylactic work, and the clearing away of filth from a street may be classified as work done for the prevention of disease What such a task implies does not seem to have been realised in Cairo.

There has been a good deal of discussion about the water-supply of Cairo among the dwellers, and a little about the drainage of the city, but what was familiarly known in England as the dustbin problem has not been agitated in Cairo. Throughout France *la question des gadoues* holds a prominent place in sanitary congresses and discussions, but in Cairo I could hardly find anyone who had taken it into consideration. As a consequence of such negligence and ignorance, Cairo is now face to face with dangers and difficulties arising from the accumulation of dustbin contents surpassing anything that I have ever seen in other towns. Though the scavenging is incomplete, because, as already ex- [illegible] maintain a sufficient staff would not be so great if disposed of in a proper manner. As a matter of fact, there is only one destructor, which only deals with a very small part of the refuse. It is inconveniently situated near the ruins of the ancient aqueduct on the way to Old Cairo, and the refuse with which it deals is difficult of destruction. In Europe there is always mixed with the household refuse a certain amount of coal or wood cinders, and this makes it possible to burn the rubbish, and the dealing with the contents of our dustbins constitutes a large industry. At one time all the rubbish was carefully sorted, but this sorting is such dirty work that many sanitary authorities have preferred sacrificing what little monetary advantage it may afford and have resorted to the much cleaner process of cremation after rough *sifting. The resulting clinkers are absolutely sterilised* by the process of fusion in the furnace and can therefore be used for road making, or in some cases are ground to powder, mixed with cement, and artificially converted into flagstones. This, however, cannot be done so readily at Cairo because there are no coal or wood cinders in the domestic refuse, and no less than 40 per cent. of the material collected is absolutely unburnable, and it contains much dust brought into the town on the feet of the camels, donkeys, and other animals that daily come to Cairo from country districts. This refuse is dragged with prongs over a grill so as to shake the unburnable matter through the iron bars into a receptacle underneath. The 40 per cent. of unburnable material was at one time sold as manure, but it contained too much salt and ammonia to be valuable. It has now been improved by mixing it with blood from the slaughter-house. The remaining 60 per cent. which can be burnt is burnt, but it consists largely of "soft-core"—that is to say, of organic matter, such as cabbage stumps, potato peelings, orange peel, and other vegetable refuse. There is not much broken glass with it and practically no coal or anything much that will fuse, and only a very poor and useless sort of clinker is produced. The refuse from the markets and from the hospitals goes directly to the destructor without being sifted. The dust-sifters are paid £1 10*s.* per month as wages, which is a higher wage than what can be earned by working on the land or as a street-sweeper in the city In England it has been found that the dangerous character of this work on account of the dirt and dust is in part compensated by the fact that it is done in the open air. In Egypt not only do these dust sorters work out of doors but they sleep in the open air, except during the two or three months of winter when it is not so warm. For this purpose they do not, however, have to hire rooms or pay rent. They collect from the refuse which they sort old oil tins which they flatten out, and with bits of old sacking and fragments of carpets make up the walls and roofs of little huts which have for their main support old poles, planks, and any other waste material that they may chance to find In these extraordinary and wretched hovels these men will sleep when the weather is exceptionally cold.

Though the clinkers produced by the destructor are not good, a powder is obtained which when mixed with water and a little lime makes a cheap inferior mortar which is a staple article used in building small native houses and known in the trade as *kosromel*. Then there is a cremation chamber which renders great service for the destruction of condemned meat and carcasses When regulations to prevent the spread of rabies first came into force the bodies of about 500 dogs were cremated here in the course of one month. Now there are not more than about 150 destroyed per month. Part of the heat of the destructor is used to generate steam which supplies the needs of the neighbouring public abattoir. Some of it is used to drive a fan which produces a blast on the furnace. Thus it may be said that in spite of the special difficulties just described satisfactory work is done by the destructors and as far as it goes we have here a solution of the problem. Unfortunately it does not go far enough

Though the scavenging work is not done thoroughly and a good deal of dirt and refuse still remains lying about, especially in some of the poorer *quarters, in small streets and* blind alleys, nevertheless about 600 cart loads are removed every day. It is estimated that these loads weigh, on an average, a third of a ton, and that 210 tons weight is carted away from Cairo every day in about 600 cart loads; but of this quantity the destructor can only deal with 30 tons per day. Only one seventh of the total is satisfactorily treated. This is an appalling fact. It should be known to every citizen of Cairo and become a subject of daily concern, and of agitation until more effective measures are adopted. A portion of this refuse is sold to the public baths and this realises a revenue of £600 a year while causing a terrible nuisance which I will describe later. The last figures I saw showed that the baths were taking 189 cartloads of refuse per day. There thus remains a growing daily accumulation of more than 300 cartloads, more than 300 cubic metres, of dirty, dangerous matter. Yet it is not treated in any way. It is not cremated, it is not even sorted or removed to any distance. Incredible as it may seem, this refuse is simply dumped down in the immediate neighbourhood of Cairo. Thus perfectly flat suburbs have been in the course *of time converted into hilly districts*, and the northern side of Cairo is now surrounded and hedged in by mountains of filth. The picturesque citadel of Cairo was pointed out to me and I was told there were cannon there that could reduce the city to ashes in a very short time. In the meanwhile, it is the city that has brought its daily output of ashes to the citadel, and the mountains thus constructed are now nearly as high as that on which the historic fortress stands. If the town were to be bombarded by the fortress some warning would be given and the inhabitants would have a chance of *escaping. The citizens of* Cairo have, however, neither respite nor chance of escape from another sort of bombardment to which they are daily exposed Here on these hills heavy artillery is constantly discharged, and it is as if more than 300 shells exploded every day, for when each of the 300 carts is tilted up a cloud arises consisting not of gunpowder smoke but of deadly dust This is taken up by the wind and carried to the streets and open windows of Cairo As this incredible state of affairs may elicit accusations of exaggeration I put in my camera as a witness. To the north of the citadel and north-east of Cairo there are such *large hills that doubtless, and judging* from a distance, most persons have mistaken them for offshoots of the Mokattam range of mountains As a matter [illegible] dust and rubbish heaps, and these [illegible] ed houses. The largest [illegible] of a railway line that has [illegible] this filth. (See Fig. 1)

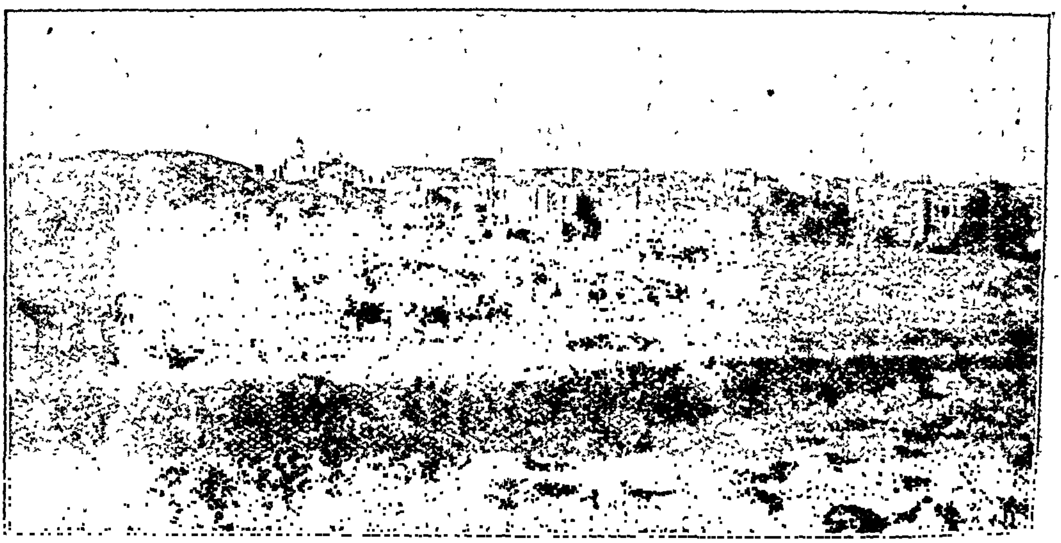
FIG. 1.



Railway passing through dumping ground upon and alongside of large mountains of rubbish.

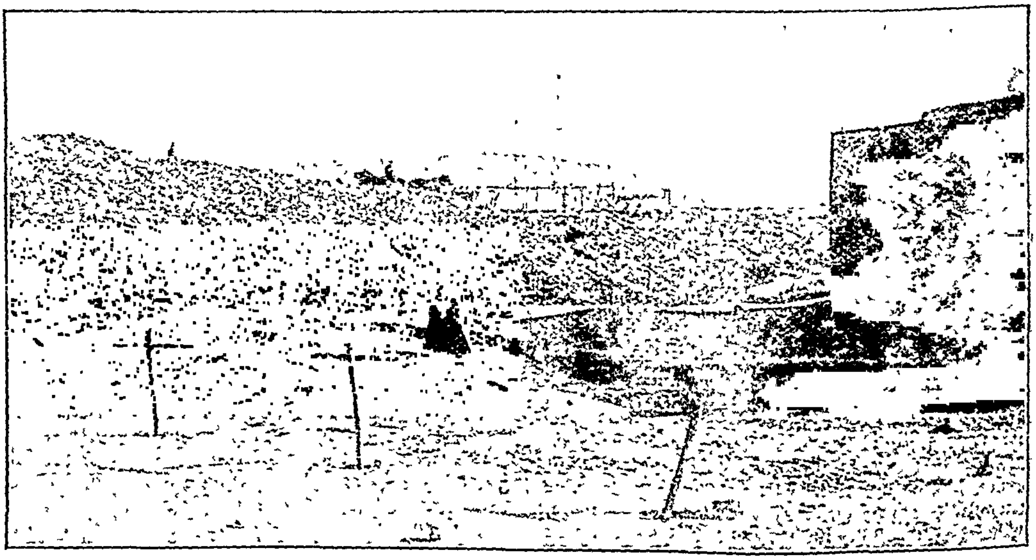
Here it assumes the proportions of a veritable mountain. Another of my photographs shows some of the scavengers' carts commencing the ascent of these hills. (See Fig. 2.) The road is made of rubbish, and on both sides the household refuse accumulates. Formerly all this ground was quite flat. Then I have taken a photograph of the extreme limit, where empty tins, broken pots, and other rubbish comes tumbling down into a rope-walker's yard and almost against the very walls of a small factory. (See Fig. 3.) Here, making string and ropes, a number of young children are at work, and they breathe the dust fresh from these mountains of town refuse. The carriage in which I rode will be seen above the lower dust hills, the higher mountains of rubbish being seen in the distance. I shall never forget the appearance of the coachman's back. It was not possible to tell the colour of the cloth of which his coat was made. As he had remained still for some time hundreds, nay thousands, of flies had settled on the smooth expanse of broadcloth that covered the parts of his back which he could not reach to beat them off. Flies form another of the dangers created by these mountains of refuse. Not only is the dust blown from them into the town, but it forms the breeding grounds of millions of flies which convey to the town the germs they collect on the dust-heaps.

FIG. 2.



The scavenger carts bringing refuse to mountains of rubbish accumulated close to the north-east side of Cairo.

FIG. 3.



Limit of the dumping ground, where the rubbish falls into a rope-walker's yard where children are employed.

The readiness with which flies breed here is in itself a proof of the foul nature of the rubbish. But we have a further proof in the fact that it ferments and becomes so hot that spontaneous combustion sets in. These mountains of dirt are actually on fire. It is only necessary to stand still for a moment to feel the heat of the fire even through thick-soled boots, while if a walking-stick is pushed down some 10 or 12 inches the hole makes a small chimney from which smoke issues when the stick is withdrawn. Considering this phenomenon, it will be said that by spontaneous combustion all the vast accumulation of rubbish is automatically purifying itself. The best of all sterilisers—namely, fire—should render it perfectly clean and safe. Though I am not aware that any scientific experiments have been made to prove that this is so, still I am quite ready to believe that deep down in these mountains, where everything that could burn has been consumed, the heat was sufficient to sterilise what remains; but this is the work of years and does not apply to the surface. It is the newly emptied cartloads of freshly collected refuse that constitute the principal danger. Here will be found not only all the animal and vegetable matter constituting kitchen refuse, &c., but there is also some fæcal matter and specifically dangerous things, such as pus-stained rags, and f [illegible] 'ere worn by t [illegible] tes pathogenic g [illegible] ets and houses o [illegible] some private enterprise comes here with carts and workmen and pays a small sum to be allowed to cart away a little of this rubbish. This seems to indicate that it is of value as manure. It would be well if these people, instead of taking a few loads, could cart it all away, for who ever heard of surrounding—of hedging in—a town with mountains of manure!

(To be continued.)

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis and the Milk-supply.

Payment of Vaccination Officers.

The Newcastle board of guardians at one of its recent meetings had under consideration the question of payment of vaccination officers. It appears that a vacancy has arisen in the western district, and the finance committee of the board had recommended that the new officer should be paid a fee of 2*s.* 6*d.* per case instead of 4*s.* 6*d.* as hitherto. The committee stated that the average payment for vaccination over the last five years was £422 per annum for the particular district; that the minimum fee of 2*s.* 6*d.* had been fixed by the Local Government Board; that the western district had a high birth-rate; and suggested that, whilst it did not wish to interfere with the existing scale of payment in other districts, this appointment was a new one, and if paid on the lower scale a saving of £120 per annum would be made for the ratepayers. The discussion which followed on a motion to adopt the recommendation was free and apparently stormy, the advocates for the lower fee alleging that a good man could be obtained, that "medical men would tumble over each other to get the post," that when letting tenders they took the lowest, that the neighbouring town of Gateshead had adopted the lower scale, and finally, that the appointment was merely an adjunct to private practice. Those who wished the fee to remain at 4*s.* 6*d.* were emphatic in considering that the proposed change would [illegible]" that other towns, Sunder[illegible] 4*s.* 6*d.* and 1*s.* registration [illegible] Middlesbrough paid 5*s.* and 1*s.*; Alnwick and Felton, 7*s.*; the Castle Ward of Northumberland, 7*s.* 6*d.*; and in London fees were paid up to 10*s*; that the fees of the new officer could hardly be changed without also lowering those of the officers of the other districts. The resolution to adopt the half-crown rate was defeated by 22 votes to 18, one member not voting. An amendment that 3*s.* 6*d.*, plus the other amounts, should be paid was also lost by 20 to 15. The rate therefore is to remain at 4*s.* 6*d.* per case.

Royal Victoria Infirmary.

A quarterly Court of Governors of the institution was held on May 27th at the infirmary, Sir Riley Lord presiding. Sir Thomas Oliver was reappointed an honorary physician and Sir Riley Lord was made a president of the infirmary. The latter, in his remarks to the meeting, alluded to his hope that the institution might at no very distant date be in the possession of a convalescent home, to which patients might be sent to continue their treatment after their short stay in the building, which shortness was necessitated by the pressure on the beds. The financial statement was presented to the court, and showed that the average number of patients in the infirmary for the past four months had been 654, as against 619 in the corresponding month, of last year. The total income for the same period was £10,815, against £8969 last year, while the total expenditure for the period had been £10,952, as compared with £10,276 last year. The expenditure therefore exceeded the income by £137, while last year for the same months the deficit was £1307. The contributions made by the workmen of the district continue to increase.

June 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

[illegible]

[illegible] Ro[illegible] ment showing that the increase in the price of alcohol proposed in the Budget would affect the infirmary to the extent of £112 per annum. This increase was only to a small extent due to the use of alcohol as a beverage, but applied to preparations in which alcohol was used. For anæsthetics alone it meant an increase of £50. The result of the tax meant practically an increase of 10 per cent. on drug expenditure. A letter was read from Dundee Royal Infirmary asking support to get some concession in regard to the making of tinctures and other pharmaceutical preparations. The subject was remitted to the medical committee for report. A proposal by Dr. A. Veitch of Gilmore-place to provide motor-car rides for patients on Wednesdays was accepted with thanks. Dr. Veitch made similar arrangements last year, which were successful and highly appreciated. Dr. Veitch has interested a number of private motor-car owners in his scheme, who have readily placed their cars at his disposal for the purpose. He hopes to make the scheme big enough to include the nursing staff if possible.

Complimentary Dinner to Dr. Stuart Macdonald, Edinburgh.

Dr. Stuart Macdonald, who was recently appointed to the lectureship on pathology in the Newcastle School of Medicine, was entertained, on the evening of June 3rd, by a number of his friends and colleagues in Edinburgh at a dinner in the Caledonian Station Hotel. Dr. Alexander Bruce occupied the chair. Dr. Macdonald has been for a number of years an extra-mural lecturer and teacher of pathology in the Edinburgh school. He was for a time an assistant pathologist at the Royal Infirmary, and up to the present was pathologist to the Royal Hospital for Sick Children. He is a graduate of Edinburgh, and has made valuable contributions to the literature of epidemic cerebro-spinal meningitis and of delayed chloroform narcosis. He leaves Edinburgh with the hearty good wishes of his Edinburgh colleagues for a prosperous and distinguished career in connexion with the North of England School of Medicine.

The Edinburgh Royal Maternity Hospital.

The annual meeting of the supporters of this charity was held on June 3rd, Principal Sir William Turner, K.C.B., presiding. Dr. J. W. Ballantyne, submitted the report. The number of patients treated in the hospital was 549; at their own homes 663; at the Leith branch 437. There had been during the year 13 maternal deaths among the indoor cases, none among the outdoor. 46 nurses were trained and training had been given to 47 students. The financial report showed that the income had been £1902 and the expenditure £2316. During the year the Early Notification of Births Act had come into force and the medical staff had aided the health officer of the city by supplying him with information which enabled the health visitor to get in touch with patients who had been in hospital. The directors were satisfied that benefit would accrue to mothers and infants by this arrangement.

Tuberculous Patients at Edinburgh City Hospital.

It is gratifying to be able to record that the public health committee, which is ably presided over by Dr. G. M. Cullen, has agreed to recommend to the town council that the number of beds at the City Hospital for cases of pulmonary phthisis be increased from 50 to 62, and that six pavilions for the open-air treatment should be provided. Any increased accommodation for these cases will be welcomed by those who know the needs of a city like Edinburgh.

Conference on Medical Supervision of School Children in Lanarkshire.

The Lanarkshire authorities are making an effort to organise the medical supervision of school children in the county on a satisfactory and businesslike basis. As a first step in the process the secondary education committee of the county has asked the county council that the scheme be given the assistance of the county medical officer. The idea is to have at the head a man who will be in no competition with local practitioners. It is suggested that he should supervise the beginning of the scheme, and afterwards, when it is organised, his work will resolve itself into mere direction. Details of the scheme have been given in a circular forwarded to the school boards of the county, and a conference of the authorities interested in the matter was held last week. At this conference 35 out of the 48 school boards of the county were represented, and it was decided that the scheme would be proceeded with if the committee received a certain number of favourable replies from the various boards after the proceedings at the conference had been reported to them. It is estimated that the number of children who will have to be medically examined amounts to three-eighths of the total school population. That means that 38,193 children in the county will fall to be examined, and it is considered that a staff of from five to seven medical inspectors will be required. Assuming the coöperation of all the school boards in the county the cost will lie between £2500 and £3000 per annum. A full staff may not be necessary at first, but whatever the cost may be the expense will fall upon each board in a proportion based upon the average number of scholars on the register. The county will be divided in such a way that each part will receive an efficient service.

Proposed Paisley Lunacy District.

The parish council of Paisley has decided to approach the General Board of Lunacy to have Paisley parish formed into a lunacy district. Formerly in its asylum at Riccartsbar it has been in the habit of receiving boarders from the various parishes round Paisley, but these parishes have now combined and built an asylum at Dykebar. As boarders have been a source of considerable revenue in the past, if the parish were converted into a lunacy district the council would be in a position to make up to a certain extent the deficiency.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in Dublin: Suggestions of the Public Health Committee.

THE public health committee of the Dublin corporation has just issued its report (June 5th) on the subject of tuberculosis in Dublin. It refers to the fact, already brought to light on several previous occasions, that "very often consumptives sleep in the same room, and sometimes in the same bed, with healthy members of their families," and indicates the obvious truism that this "close contact of persons suffering from pulmonary tuberculosis is no insignificant factor in spreading this formidable disease." The medical superintendent officer of health has suggested the providing of a separate room for the consumptive; and that such rooms should be constituted "temporary places for the reception of the sick," under the provisions of Section 155 of the Public Health (Ireland) Act, 1878. The report states that in 1908 956 persons died from pulmonary consumption in the City of Dublin. The great majority of the deaths occurred among the poorer classes, especially in the families occupying single-room dwellings. The provision made for consumptives in our metropolitan hospitals is small in comparison with the number of persons affected with pulmonary tuberculosis. Then the joint sanatorium which is shortly to be erected will accommodate some 50 patients only, at a cost of about £5000 per annum. The report expresses the belief that "on an average a room for the reception of a consumptive person will not cost more than 2*s.* 6*d.* per week, or £6 10*s.* a year. The equipment as bedroom would not exceed £3 10*s.*" It proceeds to state that if the committee were "empowered to expend £200 a year in hiring, equipping, and maintaining rooms 20 consumptives could be provided for," adding the suggestion that this sum should be placed at its disposal "as a tentative effort to lessen, in the direction indicated, the spread of tuberculosis." The persons provided for would, in most cases, be those employed in some industrial occupation; occasionally a consumptive after return from hospital or sanatorium. The suggestion is surely a feasible one, and in the present state of affairs it is worthy of a fair trial.

Health of Belfast.

At a meeting of the city corporation of Belfast held on June 1st it was reported that between April 18th and May 15th, 1909, the death-rate from all causes in Belfast was 20·0, 7·8 from chest affections, and 0·8 from zymotics per 1000. There is a marked diminution in fever cases (especially typhoid), but the mortality from chest affections is in excess of the normal rate. In reference to the late Health Commission the finance committee reported that it had informed the Local Government Board that, acting on counsel's opinion, it felt it was not liable for a sum of £600, but the Earl of Shaftesbury, who is one of the aldermen, spoke very decidedly against entering into litigation with the Local Government Board. Neither the Local Government Board nor the Treasury forced the Commission on them, he said, but a number of their own citizens, and they had already agreed to pay the principal portion of the expenses, and the present sum in dispute was only £600. Lord Shaftesbury said that the idea was that the corporation was not to pay for those members of the Health Commission who came from outside Ireland (Colonel Harding, the chairman, Dr. A. K. Chalmers of Glasgow, and Dr. L. W. D. Mair of London), but he said it was of great advantage to the city to have these men. Everyone would surely admit that their expert knowledge was a real asset in such an inquiry, and the result was that they obtained as good an opinion regarding the health of the city as could possibly be had. They must agree that the result of the inquiry was of great benefit to the city. Was it, therefore, dignified—was it a very high attitude to take up—to say, "We paid £800, but we won't pay the other £600"? It was not edifying for an important city like theirs to assume this attitude, which implied, "We admit that the Commission was of benefit and that the report was of use, but we won't pay this £600." Alderman Sir James Henderson, D.L. (an ex-mayor), in supporting Lord Shaftesbury, said the three gentlemen of the Commission, namely, Colonel Harding, Dr. Chalmers, and Dr. Mair—in respect of whose expenses this sum of £600 was in dispute, were of the greatest possible assistance as members of the Commission; in fact, he did not think they could have done without them. Ultimately, the chairman of the finance committee was obliged to take the matter back, and a special meeting of the corporation is to be called to decide the question in order that there shall be no more delay.

Royal Victoria Hospital, Belfast.

Saturday, May 29th, was "Hospital Saturday," and £720 have been paid in already, which is about the same sum as was paid at the corresponding date of last year.

The Kelvin Statue.

The acrimonious dispute regarding the site for the statue of Lord Kelvin was settled on June 2nd, when at a public meeting of subscribers held in the Belfast City Hall (the Lord Mayor presiding), the Chancellor of the Belfast University (the Earl of Shaftesbury) withdrew the claim made by the University, and it was unanimously decided to place the memorial in the grounds of the City Hall.

The Dufferin Children's Hospital.

The new institution now known as the "Dufferin Children's Hospital," in connexion with the Belfast workhouse, was appropriately opened on June 3rd by Lady Hermione Blackwood, youngest daughter of the late Marquis of Dufferin and Ava. The building, which stands on a beautifully open and healthful position isolated from the other buildings on the workhouse premises, is three storeys in height, built of red brick, with balconies in front, and has eight wards to accommodate altogether 200 children. Children suffering from complaints making it necessary can be isolated, not alone in the wards but in the lavatory annexes. The windows are suitably guarded and there are special exits in case of fire or emergency, and a special system of heating and electric lighting has been installed. Altogether the whole surroundings and the arrangements provided in connexion with the hospital have been so carefully thought out and the details so completely executed as to reflect the highest credit on the guardians, especially the lady members. The chairman of the board of guardians (Mr. J. S. Bryars), who presided, having welcomed Lady Hermione Blackw [illegible] which that lady formally opened [illegible] on the importance of looking [illegible] moral improvement of children. Sir John Byers, in moving a vote of thanks to Lady Hermione Blackwood, joined with her in complimenting the members of the Belfast board of guardians on their splendid medical work. They were the first body of their kind in Ireland to isolate consumptives, and they had erected a sanatorium which was a credit to them and to Belfast and an example to the whole of Ireland. They had also built a maternity hospital, a nurses' home, and, to crown all, on that day those present had an opportunity of seeing opened the largest and best-equipped children's infirmary in Ireland. Miss J. Clark seconded the vote, which was very enthusiastically carried. Subsequently the members of the board and the large number of visitors present were hospitably entertained to afternoon tea by Mr. J. S. and Mrs. Bryars.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Pierre Budin Foundation.

THE inauguration of the building of this foundation took place on May 24th under the presidency of M Emile Loubet, late President of the Republic. The establishment is organised for the reception of infants accompanied by their mothers The infants will be weighed and examined periodically by physicians, who will overlook and give directions for their upbringing. Suckling by the mother will be held up as the most suitable method of feeding, but in case of need this will be supplemented or replaced by distributions of milk. Madame Budin was present, and M. Paul Strauss, senator and president of the institution, spoke first, and gave an account of the objects of the foundation. Afterwards M. Leon Labbé, M. Maygrier, M. Henri de Rothschild, and M Landouzy gave details of the life and work of Professor Budin. Then M Lionel Laroze recited an ode by Jean Richepin to the memory of Budin. M. Loubet wound up the proceedings by appealing to all those present to aid in the salvation of infant life. After the meeting the various buildings were inspected.

The Destruction of Tubercle Bacilli in Bread

At a meeting of the Society of Biology held on May 15th M. Auché gave an account of some experiments which he had made as to the destruction of tubercle bacilli in bread. He mixed some tuberculous sputum with dough, which was then baked. Apparently the heat of the baking destroyed the bacilli, for guinea-pigs which were inoculated with a bouillon made with some of the bread-crumb were not infected with tubercle. M. Auché does not, however, consider that this experiment proves that bread made from tuberculous dough is necessarily safe, for in the case of large loaves the central parts may not always attain the temperature necessary for the destruction of the bacilli, and besides the temperature at which bread is baked varies in different bakeries.

An Old Soldier and Unqualified Practice.

The Association of Medical Men of the Seine has recently prosecuted an old soldier, aged 81 years, a Zouave named Jacob, for illegal practice of medicine. The tenth Chamber of the Tribunal, the court which heard the case, has just given judgment. The judgment states that the Zouave was prosecuted for having habitually taken part in the treatment of sick persons, that clothed in a white robe he showed himself to those who came to consult him, that he fixed his eyes on them and invoked certain spirits whom he called "superiors," that he asked his patients no questions, neither did he prescribe any particular *régime* nor any remedies. The rest of the picturesque description of the Zouave's behaviour notes that he used to pass between the benches upon which his visitors were sitting and touch them lightly with his hand; that he collected such moneys as they were willing to give, but that such offerings were entirely voluntary; and that the séance terminated by his advising them in general terms to drink neither wine nor alcohol, to eat nothing but vegetables, and never to take any drug. As he always did the same thing and took no heed of what was supposed to be the matter with his visitors Jacob could not be held to "treat the sick," and the court found therefore that there was no violation of the law. The syndicate of medical men therefore had to pay the costs.

An Experimental Research on the Method of Action of "Altitude Cures."

At the Hospitals' Medical Society on May 28th M. G. Russ read a paper on a study which he had made to determine the effects on the respiratory and circulatory and metabolic functions during a long stay at a high altitude The subjects of the experiments remained in good health and only suffered from mountain sickness in an insignificant degree. Study of the respiratory exchanges at rest and in the course of the least effort at muscular work showed that the hypothesis of an increased metabolism (*combustion intra-organique*) in high mountain climates cannot be upheld. Even at the considerable altitude of 4350 metres the respiratory exchanges remained the same as at sea level, all other conditions being equal. The increase in pulmonary movement in a person at rest is nearly constant at a high altitude, but in the majority of cases it is inconsiderable, even at the height already mentioned. It is not necessarily accompanied by an increase of amplitude in the inspirations, and very often it only constitutes an extra exertion for the person without any compensatory advantages in aerating the ineffective regions of the lung. On the other hand observations made on healthy people should not be applied too hastily to sick ones, especially to tuberculous patients whose pulmonary movements are always exaggerated. Muscular work done at a height causes a much greater increase in the "respiratory debit" than when it is performed at sea level. Mountain walks form the best method of rendering an atelectatic lung, or one bound by adhesions, permeable to air. In four guinea-pigs kept for 24 days at Chamounix and nine days in the observatory at the top of Mont Blanc, M. Russ and M. Davesne were unable to determine any considerable erythrocythæmia by taking blood from the heart. The appearance of a small number of nucleated red corpuscles in these animals is apparently due to the effect of cold and not to any excitation of the hæmatogenic bone marrow by the deficiency of oxygen in the blood. At high altitudes inhalation of oxygen constitutes the specific treatment for mountain sickness and is an immediate cure for slight attacks. This procedure only influences respiratory movements in a transitory manner, but exercises a very marked action on tachycardia due to altitude. Acclimatisation to the rarefied air of mountain heights is essentially a process of accustoming the nervous centres to deficiency of oxygen in the blood-stream.

Subcutaneous, Intramuscular, and Intravenous Injections of Alkaline Mineral Waters.

M. Fleig communicated a further note on his researches into this subject to the Therapeutical Society on May 26th. He has injected into the veins of men the waters of Vals, Châtel-Guyon, and Saint Nectaire in doses of 200 cubic centimetres without making them isotonic, and up to 400 [illegible] that precaution. These facts prove [illegible] nous injections of alkaline [illegible] purposes on a large scale. M Fleig proposes to make the waters isotonic by using sugar when they contain substances chemically incompatible with salt.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A Simplified Serum Reaction for Syphilis.

Dr. Schürmann, of the Institution for Experimental Therapy in Düsseldorf, writing to the *Deutsche Medizinische Wochenschrift*, says that in the course of attempts to modify Wassermann's reaction for syphilis he has found that the lactic acid is of importance for the reaction, but that it cannot be ascertained by the usual Uffelmann reagent because of the presence of hæmoglobin in the serums. He has now devised another way in which 0·1 cubic centimetre of serum is diluted in 3 cubic centimetres of a solution of chloride of sodium of 0·8 per cent. strength and a drop of perhydrol is added. The serum is then mixed with 0·5 cubic centimetre of a reagent consisting of 0·5 part of phenol, 0·62 part of a 5 per cent. solution of chloride of iron, and 34·5 parts of distilled water. This reagent is of a blue-violet colour, and can only be kept for a very short time even in a stoppered bottle. Normal blood serum brought into contact with the reagent shows only a slight greenish hue on the top, which completely disappears on shaking, the mixture being left absolutely clear and transparent. With syphilitic serum the reaction is quite different, for when it is mixed with the above reagent a brownish-black colour appears, which becomes still more intense on shaking the glass. Syphilitic serum, moreover, froths after being brought into contact with the reagent. The reaction becomes visible in from one to two minutes. Up to the present time 84 samples of serum have been examined by this method, the result being that serums which showed a positive Wassermann reaction turned the reagent dark brown. Serum from scarlet fever patients did not give a positive reaction; the serum of sheep, guinea-pigs, and rabbits also proved negative.

Collective Investigation on Appendicitis.

The Berlin Medical Society some time ago made arrangements for a collective investigation into the cases of appendicitis which happened in 1907, and the results of the investigation were communicated at a recent meeting of the society by Professor Albu and Professor Rotter. Professor Albu said that the number of cases of appendicitis had increased enormously since the "nineties" of last century. Whilst in the year 1897 there were only 1847 cases registered, the number rose to 3081 in the year 1902 and to 6061 in the year 1907. It has been alleged that the increase was apparent rather than real, being in actual fact due to improvements in diagnosis. This argument was true only to a certain extent, but the increase in the number of cases could not be accounted for wholly by improvement in diagnosis, and the explanation undoubtedly was that the disease has become endemic. Of the patients suffering from acute appendicitis 9·3 per cent. were under 10 years of age, 34 per cent. were from 10 to 20 years, 29·6 per cent. were from 20 to 30 years, 17 per cent. were from 30 to 40 years, and 10 per cent. were above 40 years. For chronic appendicitis the acme was in the age period from 20 to 30 years. With regard to the etiology, it was stated that previous infectious diseases were only seldom registered; an accidental injury was acknowledged in only three cases. The cause of the disease was apparently enterogenic. In 55 per cent. of the cases there was *constipation, in 62 per cent. there was pyrexia, and in* 57 per cent. there was increased frequency of the pulse. Suppuration developed in 2 per cent. of the acute cases. Dr. Rotter, referring to the therapeutic results, said that 2705 cases of acute appendicitis had been registered, of which 2365 were treated in hospitals and 340 at home. In the first category there were 214 deaths, or a mortality of 9 per cent.; in the latter category there were six deaths, or a mortality of 1·7 per cent. There were 1344 cases operated on, with 197 deaths, or a mortality of 14·6 per cent. With regard to the stage at which the operations took place 105 were performed on the first day, with one death, or a mortality of 0·9 per cent.; 318 were performed on the second day, with 23 deaths, or a mortality *of 7 per cent.; the entire mortality of the two first days* being therefore 5·6 per cent. On the third day 238 operations were performed, with 23 deaths, or a mortality of 10 per cent.; and after the third day 683 operations were performed, with 150 deaths, or a mortality of 20 per cent. The death-rate following operations after the second day was therefore 18·8 per cent. In cases under ten years of age the death-rate was 17·4 per cent., from 10 to 20 years it was 5·3 per cent., from 20 to 30 years it was 10 per cent., from 30 to 50 years it was 21·7 per cent., and above 50 years it was 80 per cent. Operations *à froid* have been performed for chronic appendicitis in 87 cases, and during an interval in 805 cases, the actual number of deaths being nine, or a mortality of 0·9 per cent. The best results were obtained by early operations.

Congress of Naturalists and Medical Men.

The forthcoming meeting of the German Association of Naturalists and Medical Men will be held at Salzburg in Austria from Sept. 19th to 25th. In addition to the scientific proceedings, the programme of the meetings includes as usual a variety of social entertainments. The ancient and celebrated city of Salzburg, with its splendid alpine surroundings, will certainly attract many visitors from Germany, Austria, and abroad. After the meeting excursions will be made to the well-known health resorts of Reichenhall and Gastein. Medical men desiring to take part may apply for further particulars to the local committee or to Dr. Würtenbergen in Salzburg.

June 7th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Vaccine Complicated with Foot-and-Mouth Disease.

THE Bureau of Animal Industry of the United States Department of Agriculture has published the results of an investigation as to the origin of an outbreak of foot-and-mouth disease among cattle which prevailed during the early part of last winter. It was found after very careful investigation that it had its origin in calves used for the propagation of small-pox vaccine virus which had been contaminated with the virus of foot-and-mouth disease. The contaminated virus was traced to vaccine which had been imported from a foreign country. The disease was finally traced to calves that had been used for the cultivation of vaccine virus by a large Detroit firm. On further inquiry it appeared that this firm had secured a supply of vaccine virus which was imported by a firm in Pennsylvania. From the stockyards of the Detroit firm, where the calves which had developed the disease were kept, the disease spread widely. The cattle which were vaccinated by the virus from both of these firms all developed the foot-and-mouth disease. The laboratories of the Public Health and Marine Hospital Service immediately began an examination of all the supplies of vaccine virus in the country and now report that there is no impure vaccine on the market.

The Proposed National Public Health Department.

The efforts to secure the establishment of a National Public Health Organisation have resulted in the designation by the President of the Surgeon-General of the Public Health and Marine Hospital Service as a special commissioner to prepare a plan by which all of the agencies of the Federal Government which have duties relating to the public health may be consolidated into one department. The department over which the Surgeon-General presides, "The Public Health and Marine Hospital Service," has been doing excellent national sanitary work, and only requires such reorganisation as will enlarge the scope of its jurisdiction, increase its equipment, and give it adequate powers to make it a most efficient department of health. The proposition which meets with most favour is the consolidation of several bureaux, having duties which nearly or remotely relate to the public health, and now scattered among the other departments, into an independent public health organisation. This plan would be most readily effected if the Public Health and Marine Hospital Service were taken as the unit in the consolidation act and the various allied branches of public health service were incorporated in its organisation. *This method of securing an* adequate National Public Health Department meets with general professional approval, and it is anticipated that the Surgeon-General will finally report such a scheme to the President.

Tuberculosis Increasing in Rural Districts.

The New York State Department of Health reports that tuberculosis is increasing in the rural districts and diminishing in the cities of the State. On the basis of the average for five years from 1901 to 1905, the death-rate in the cities of the State fell from 203·5 to 185 per 100,000, while in the country districts there was an increase from 112·7 to 123 per 100,000. This remarkable difference in the death-rate from tuberculosis of the two classes of people is attributed to the stringent sanitary measures adopted and enforced by the health authorities of cities as compared with the rural districts. Somewhat of this change is undoubtedly due also to the campaign of education which has been in progress in the cities by means of lectures and exhibitions.

The Transmission of Germs by the Mails.

The United States Post Office Department has adopted stringent measures in the transportation of pathological specimens to avoid the possibility of the transmission of the germs of disease to those engaged in the service. In the first place, the postal service will handle cultures or specimens only when destined to United States State or municipal laboratories. Specimens intended for medical laboratories other than public institutions must be transmit [illegible] ltures or cultures of [illegible] at ordinary temper [illegible] unmailable; such specimens may be sent in media that remain solid at ordinary temperature. On the outside of every package of diseased tissues admitted to the mails shall be written or printed the words: "Specimen for bacteriologic examination; this package to be treated as letter mail." No package containing diseased tissues shall be delivered to any representative of any said laboratories until a permit shall have first been issued by the Postmaster-General certifying that the said institution has been found to be entitled, in accordance with the requirements of this regulation, to receive such specimens. Minute rules are given in regard to the construction and preparation of packages used for conveying through the mails pathological specimens, in the moist and in the dry state, for bacteriological examination for diagnosis in cases of suspected diphtheria, tuberculosis, and other communicable diseases.

Decline of Attendance on a Homœopathic School.

The University of the State of Minnesota has maintained for 20 years a separate homœopathic department, devoted to teaching all the medical courses of the junior and senior years. Latterly the attendance has gradually declined until but three students made up the class. The regents of the University have recently abolished the homœopathic department, and created two elective chairs in homœopathic materia medica and homœopathic therapeutics. It also provided that students electing such instruction should be granted diplomas specifying that they were in homœopathic medicine.

Honouring the Memory of Dr. Ephraim McDowell.

The American Gynecological Society, at its recent meeting in this city, celebrated the centennial of Dr. Ephraim McDowell's first operation of ovariotomy by a banquet. A memorial address was given by the President of the society, Dr. J. Riddle Goff, and addresses were given on the "Successors of McDowell" in America and in Europe.

May 26th.

Medical News.

UNIVERSITY OF OXFORD: DIPLOMA IN OPHTHALMOLOGY.—The Board of the Faculty of Medicine gives notice that it has approved the following regulations for the diploma in ophthalmology (see Statute approved by Convocation on May 11th, 1909, *Gazette*, p. 614):—

1. The examination shall be conducted partly in writing, partly *viva voce*, and shall be partly practical. The subjects of the examination [illegible]

[illegible]

5. Candidates must have their names on the Medical Register of the United Kingdom, or, if they are graduates in medicine of universities [illegible]

[illegible] observed.

8. Any candidate who has failed to send in his name as above prescribed shall be permitted to do so up to the seventh day before the commencement of the examination on payment of an additional fee of [illegible] the depart- [illegible] the depart- [illegible]

FOREIGN UNIVERSITY INTELLIGENCE.—*Athens:* Dr. N. Kephallinós has been appointed Extraordinary Professor of Children's Diseases.—*Berlin:* Dr. Felix von Luschan, who was for some years a surgeon in the Austrian army in Bosnia, has been appointed Professor of [illegible] *nsbruck:* Dr. [illegible] *of Anatomy.* [illegible] f Physiology, [illegible] Dr. Arnoldo Canta [illegible] of Medicine.—*New* [illegible] Dr. Theodore C. Ja [illegible] edical College, has been appointed Professor of Medicine.—*Rome:* Dr. Canzio Ricci has been recognised as *privat-docent* of Psychiatry, and Dr. Vasco Forli as *privat-docent* of Neurology and Psychiatry.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual meeting of the Fellows was held on June 5th, Mr. J. Lentaigne, the President, being in the chair. A favourable report was submitted. During the year 19 candidates having passed the examination were admitted Fellows, 48 obtained the Licence, 27 the Diploma in Public Health, 16 the Licence in Dental Surgery, and 70 passed the entrance examination. The obituary list showed that eight Fellows [illegible] There are at present [illegible], 303 Diplomates in [illegible] Dental Surgery. At a meeting of the Fellows held on June 7th the following were elected for the ensuing year:—President: Mr. John Lentaigne. Vice-President: Mr. Robert H. Woods. Secretary of the College: Sir Charles A. Cameron, C.B. Council: Sir Henry R. Swanzy, Mr. William Stoker, Sir Charles Alexander Cameron, C.B., Mr. John B. Story, Sir Charles B. Ball, Sir Thomas Myles, Sir Arthur Chance, Mr. Richard D. Purefoy, Sir Lambert H. Ormsby, Mr. Henry G. Sherlock, Mr. R. Bolton M'Causland, Mr. R. Lane-Joynt, Mr. William Taylor, Mr. Edward H. Taylor, Mr. G. Jameson Johnston, Mr. R. Charles B. Maunsell, Mr. William Ireland Wheeler, Mr. D. Edgar Flinn, and Mr. Thomas E. Gordon.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Charles Morrison of Basildon the London Hospital will receive £10,000.—The late Mrs. Annie J. Holborn [illegible] £5000 to St. Bartholomew's [illegible] Dispensary and Children's [illegible] el" cot, £500 to the Home [illegible] and £200 to the Medical [illegible] Women's Settlement at Canning Town.

West London Medico-Chirurgical Society.—The annual conversazione and Cavendish lecture will be held at Kensington town hall on Friday, June 25th, at 8 o'clock. Lecturer: Sir Victor Horsley. Subject: The Cerebellum.

Literary Intelligence.—A new edition of Dr. F. W. Burton-Fanning's "Open-air Treatment of Pulmonary Tuberculosis" (Modern Methods of Treatment Series) is announced by Cassell and Co., Limited. In this edition the author deals with the researches of Sir A. E. Wright and his collaborators as well as with the new methods of early diagnosis, including Calmette's ophthalmo-reaction.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. P. Katchkoffski, *privat-docent* of Surgery in the University of Kieff.—Dr. Bourneville, physician to the Bicêtre.—Dr. Ludwig Hoffer von Sulmthal, extraordinary professor of medicine in the University of Gratz.—Dr. A. Pinner, extraordinary professor of chemistry in the University of Berlin, at the age of 67 years.

St. Paul's Eye Hospital, Liverpool: Ophthalmia Neonatorum.—At the annual meeting of the supporters of St. Paul's Eye Hospital references were made to the new departure made in the direction of special measures for the treatment of ophthalmia neonatorum and the prevention of subsequent blindness. The scheme had been warmly commended in the memorandum appended to the report of the committee of the British Medical Association, and had there been described as an almost ideal method which might well be imitated in other large cities. It was also stated that the Local Government Board had sent a request for particulars, and evidence had been given before the Parliamentary committee appointed to consider the working of the Midwives Act. The cases of ophthalmia neonatorum treated in the hospital during the first year were 75, and during the first four months of 1909 53. The ward now contains four beds for mothers and four cots. The accommodation having proved insufficient the committee appealed for funds to rebuild the hospital on a site opposite the David Lewis Northern Hospital. A special feature of the new hospital is to be the extra accommodation for children with a view to the prevention of blindness. There will be an ophthalmic ward of ten beds and ten cots, and two wards (including isolation rooms) of ten beds each for boys and girls respectively. It is proposed that this department shall be designated the "George Edward Walker Memorial Children's Department," in memory of the late senior surgeon. The cost of reconstruction will be about £13,000, of which sum £6000 and the value of the land were already promised or given. It was agreed to call the institution in the future "St. Paul's Eye Hospital," and to cease to treat diseases of the ear.

The Society for Training Teachers of the Deaf and for the Diffusion of the Oral System.—The annual general meeting of this society, which advocates the use of the German or "pure oral" system of speech, was held, by the kind permission of Mrs. and Dr. H. E. Symes-Thompson, at 33, Cavendish-square, W., on May 26th. Sir Melvill Beachcroft, chairman of the London County Council, presided, and in the course of a very interesting address said that the society had been doing its best for 30 years to train and send out qualified teachers of the deaf on the pure oral system. 25 years ago the Royal Commission on the Deaf had recommended that the training colleges for teachers of the deaf should receive at least an equal grant to that given to the ordinary training colleges, but no grant had been given (except in the case of the "third year student"), and they were to a very large extent dependent on voluntary aid. It was remarkable, he said, that the State should be backward in assuming the fullest responsibility in regard to the deaf and the blind; and though deafness is perhaps a greater misfortune than blindness, as it isolates the sufferer more completely from society, more has been done, and is being done, for the blind in this country than for the deaf. He hoped that as a result of the meeting increased interest would be shown in the efforts of this institution to provide the means for teaching the dumb to speak and the deaf to read. Mr. P. Macleod Yearsley, medical inspector of the London County Council deaf schools, and honorary lecturer on anatomy and physiology at the society's training college, urged the necessity of deaf children remaining longer at school. Mrs. Arthur Kinsey, late lady-superintendent of the training college and school, described how deaf children were taught to speak. Miss Mary Johnston, lecturer on the training of the speaking voice, Dr. G. E. Shuttleworth, and Mr. B. St. John Ackers, founder of the society, also spoke, and the usual votes of thanks brought the meeting to a close. The college and school at Eaton Rise, Ealing, are open to visitors on Tuesdays during term.

Hygiene in Elementary Schools.—The following motions were unanimously carried at a meeting of the Council of the Metropolitan Counties Branch of the British Medical Association on May 27th:—

1. That the Council of the Metropolitan Counties Branch of the British Medical Association, represent[illegible] 2700 [illegible] of the medical profession resident in, [illegible] London, would respectfully urge on [illegible]: also on all boards of managers of elementary schools in London, that, in view of the questions of physical welfare which will be undertaken by the school care committees and the local associations of care committees about to be formed, it is desirable to include in the membership of each of those committees one or more registered medical practitioners.

2. That a copy of the [illegible] divisional correspondents of the London County Council; (4) the honorary correspondents of non-provided Church schools; (5) the clerks of all borough councils in London, with an appropriate covering letter in each case; also to (6) The Lancet and *British Medical Journal* and any other suitable medical or nursing journal.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The End of the Whitsuntide Holidays.

Many Members of Parliament prolonged their holiday for a few days after Thursday, June 3rd, when the House of Commons resumed its sittings. In fact, the attendance on Thursday was one of the smallest seen for many a day. However, the sitting was not wasted. The Government was able to get one of the allotted days of supply, and in the crowded condition of the Ministerial programme every day is precious. The expectation is prevalent that the session will extend into September, if not into October. The Finance Bill will take precedence over other measures, and Members who are interested in the Housing and Town Planning Bill and Mr. Burns's Milk Bill are beginning to regret that more progress with them was not made in the early part of the session. It is too soon to write confidently of their ultimate prospects of becoming law this session. Opposition to Bills, unless they excite widespread controversy, is apt to become languid in July and August. Thus it is remarkable how many Bills a Government will pass through their remaining stages in a very few weeks towards the end of a session, when Members are anxious to be released from attendance to their Parliamentary duties.

Dr. Newsholme's Annual Report.

The publication of the annual report of the medical officer of the Local Government Board is usually delayed a considerable time. Dr Arthur Newsholme's report for the year 1907-08 is only now issued as a Parliamentary paper. It [illegible] tive business of the medic[illegible] several reports dealing with important problems of public health from the pens of other medical officers. Dr. Newsholme himself indicates the work which the medical department of the Local Government Board has done. He states that, as in past years, it has sought to extend its usefulness by obtaining and disseminating knowledge. It has held conferences with local authorities and their officers with reference to such matters as the prevalence of disease, hospital construction, local by-laws, and the appointment of officers. Advice and assistance have been directly rendered to local authorities by the visits of medical inspectors. Formal inquiries have been held by these officers into such matters as the combination of districts for hospital and other administrative purposes, loans for hospital sites and buildings, local by-laws, and schemes for water-supply and sewage disposal. Other sections of Dr. Newsholme's own report deal with vaccination, plague, cholera, and auxiliary scientific investigations.

Industrial Poisoning.

Dr. Thomas M. Legge, H.M. medical inspector of factories, has written a report which deals largely with the cases of industrial poisoning occurring in 1908. It is included in the Blue-book containing the annual report of the Chief Inspector of Factories and Workshops for that year. Dr. Legge includes in his report a table setting forth in a succinct form the statistics on the cases of industrial poisoning From it it appears that 646 cases of lead poisoning were notified in 1908, and 32 had a fatal termination. Only one case of phosphorus poisoning is mentioned, and ten persons were affected by mercurial poisoning. There were 23 cases of arsenic poisoning, one of which resulted in death. 47 cases of anthrax were reported, and seven of them were fatal.

Milk and Dairies (Scotland) Bill.

LORD PENTLAND'S *Milk and Dairies (Scotland) Bill*, which is now published, must, like the Milk Bill of Mr. BURNS for England, be read in conjunction with the recently issued Tuberculosis Order of the Board of Agriculture. That Order applies to all parts of the United Kingdom except Ireland. Lord PENTLAND'S Bill provides for the appointment of veterinary inspectors by local authorities in Scotland, and the licensing of dairies. It is to be the duty of the medical officer of health, or other officer authorised by the local authority, at least once a year to inspect all dairies within a district and to make a report on them. Local authorities are to make by-laws regulating the inspection of cattle in [illegible]

Local Government Board for Scotland is given powers by the Bill to make general or special Orders. These Orders may lay down (*a*) the measures to be taken for cooling the milk and protecting it against infection and contamination; (*b*) the prohibition or regulation of the use of preservatives; (*c*) the manner of conveyance of milk intended for sale for human consumption; (*d*) the prohibition or regulation of the mixing of the milk from different churns; and (*e*) the labelling of the receptacles of milk for sale for human consumption, where the milk is sold otherwise than in its natural state. Another clause in the Bill provides for the notification of cows suffering from tuberculosis or any other disease liable to infect or contaminate the milk. The milk of diseased cows must not be sold for human food, and diseased animals must be kept apart from healthy. Persons suffering from disease of an infectious nature are precluded from assisting in a dairy. Power to take samples of milk is given to medical officers of health and veterinary inspectors. The Bill contains 27 clauses, many of which provide the machinery for carrying out its main principles.

The Housing and Town Planning Bill.

The Housing and Town Planning Bill is now awaiting its committee stage, which is to be taken in committee of the whole House. Several Members have given notice of their intention to move instructions before the committee stage is actually begun. Sir WALTER FOSTER, following up the line which he took in the debate on the second reading of the Bill, intends to move "that it be an instruction to the committee to extend the scope of the Bill so as to make provisions with respect to the appointment and duties of borough and district medical officers of health." The amendments to the Bill, of which notice has been given, fill about 22 pages of the notice paper.

The Principalship of Aberdeen University

The appointment of the Principal of the University of Aberdeen, in succession to the late Principal MARSHALL LANG, is occupying the attention of the Secretary for Scotland. Some time may elapse before the appointment is announced, but in Parliamentary circles the name of Dr. MATTHEW HAY, Aberdeen, is freely mentioned in connexion with it. It also has been stated that there is a probability that the appointment may be given to a gentleman not at present associated with the work of the University.

The Medical Acts (Amendment) Bill.

Mr. COOPER has withdrawn his Medical Acts (Amendment) Bill dealing with the subject of anæsthetics. Several Members put down hostile motions which barred its progress, but its disappearance will be only temporary. The object of the Bill was to require a medical practitioner applying for registration on or after January, 1911, to submit evidence of having received practical instruction in the administration of anæsthetics and to prohibit any person not a registered [illegible] an anæsthetic except under certain [illegible] registered as dentists before the [illegible] safeguarded. Those who are acting with Mr. COOPER on the subject of the administration of anæsthetics are anxious to have the provisions of the Bill extended as regards registered dentists. His simplest course, therefore, has been to withdraw the Bill temporarily and to reintroduce it in an amended form. The reintroduction will take place in a few days.

Public Health and Social Conditions

An interesting Blue book containing statistical memoranda and charts relating to public health and social conditions has been presented to Parliament by the Local Government Board. The volume generally has been prepared by Mr. C F. ADAIR HORE, but the Poor law and public health sections have been produced under the supervision of Mr. DAVY and of Dr. A. NEWSHOLME, the medical officer of the Board, respectively. The section relating to public health deals with the rates of mortality in the United Kingdom, European countries, and large towns, infant mortality, the principal causes of death, the mortality from various diseases, including tuberculosis, public health administration, housing and overcrowding, and the public medical service Much interesting information bearing on these subjects is given in this section.

Appointments.

Successful applicants for V[illegible] [illegible] of Public Institutions, and others possessing [illegible] for this column, are invited to forward to [illegible] directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BURGESS, MILDRED M., M.D. Lond., has been appointed Medical Officer of the Brixton Hill London County Council Industrial School for Girls.

HEATH, A. D., M.D. Lond., M.R.C.S., M.R.C.P. Lond., has been appointed [illegible] the Skin Department of the General [illegible]

HEATON, G[illegible] [illegible]n., F.R.C.S. Eng., has been re-appoi[illegible] to the General Hospital, Birmingham.

MASSON, CHARLES ARMIT, M.B., Ch.B. Aberd., has been appointed Senior Assistant Physician at Inverness District Asylum.

MCKILLOP, A. C., M.B., Ch.B. Edin., has been appointed Junior Assistant Physician at Inverness District Asylum.

MOORE, IRWIN, M.B., C.M., has been appointed Assistant Surgeon to the London Throat Hospital.

NIALL, W. G., M.D., M.S. R.U.I., has been appointed Medical Officer to the Guildford No. 2 District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BERMONDSEY MEDICAL MISSION.—Resident Assistant (female).

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £170 per annum, with rooms, fire, lights, and attendance.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Resident Medical Officer. Salary £150, with board and residence. Also House Surgeon for six months. Salary at rate of £75 per annum, with board and residence.

BOURNEMOUTH, ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.—House Surgeon, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

BRADFORD POOR-LAW HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer (female). Salary £130 per annum, with rations, apartments, and washing.

BRECON AND RADNOR ASYLUM, Talgarth, Breconshire.—Assistant Medical Officer. Salary £170 per annum, with board, apartments, attendance, and laundry.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—House Surgeon, unmarried. Salary £130 per annum, with board and residence.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon also Assistant House Surgeon, both unmarried. Salaries £80 and £60 [illegible], lodging, and washing.

CITY OF [illegible] THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, washing, and residence.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with residence, board, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Also Medical Officer and Second Medical Officer to the Casualty Department, both for six months. Salaries at rate of £100 and £40 per annum respectively with luncheon and tea.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—House Physician for seven months. Salary at rate of £60 per annum, with board, residence, and washing. Also Clinical Assistants in the Out-patient Departments.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

GLOUCESTERSHIRE EDUCATION COMMITTEE.—School Medical Inspector. Salary £250 per annum, with travelling expenses.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Also Assistant House Surgeon. Salaries £100 and £50 per annum respectively, with board, residence, and laundry.

INDIAN MEDICAL SERVICE, India Office, London.—Twenty-one Commissions.

INVERNESS, NORTHERN INFIRMARY.—House Surgeon. Salary £100 per annum, with board, &c.

IRELAND, LURGAN UNION WORKHOUSE AND FEVER HOSPITAL.—Resident Medical Officer (female). Salary £80 per annum, with apartments, laundry, and rations.

KENSINGTON AND FULHAM GENERAL HOSPITAL, Earl's Court, London, S.W.—Resident Medical Officer. Salary £50 per annum, with board, washing, and residence.

LEEDS, WEST RIDING ASYLUM, Menston.—Fourth Assistant Medical Officer. Salary £150 per annum, with board and apartments.

LINDSEY (LINCOLNSHIRE) EDUCATION COMMITTEE.—Two School Medical Inspectors. Salary £300 per annum.

LIVERPOOL INFIRMARY FOR CHILDREN.—Two Resident Medical Officers for six months. Salary in each case £30, with board and residence.

LONDON COUNTY ASYLUM, Colney Hatch, New Southgate, N.—Junior Assistant Medical Officer. Salary £160 per annum, with board, apartments, and washing.

LONDON HOSPITAL MEDICAL COLLEGE.—Assistant to the Bacteriologist and Lecturer on Bacteriology.

LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon, for six months. Salary at rate of £75 per annum.

LUTTERWORTH UNION.—District Medical Officer and Public Vaccinator. Salary £40 per annum and fees.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead.—Junior Resident Medical Officer. Salary £5[illegible] per annum, with board and residence.

NEW HOSPITAL FOR WOMEN, Euston-road.—Medical Woman to tak[illegible] Charge of X-Ray Department. Also an Anæsthetist.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Third Resident Medica[illegible] Officer. Salary £60 per annum, with board, residence, and laundry

NORFOLK COUNTY ASYLUM, [illegible] Medical Officer. Salary [illegible]

NORWICH, JENNY LIND IN[illegible] Resident Medical Office[illegible] [illegible] per annum, wit[illegible] board, apartments, and laundry.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Junior Obstetri[illegible] Assistant (Resident) and Clinical Assistants (female).

ROYAL WESTMINSTER O[illegible] William-street West Strand, W.C.—[illegible]

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—Three Clinical Assistants.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Honorary Physician.

SEAMEN'S HOSPITAL SOCIETY.—Pathologist. Salary £100 per annum, with board.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, &c.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—[illegible] six months. Salary at rate of £100 per annum, [illegible], and [illegible]

STOKE-ON-TRENT, NORTH [illegible] ARY AND EYE HOSPITAL, Hartshill.—Re[illegible] House Physician, and Junior House S[illegible] £100, and £50 per annum respectively, with apartments, board, and washing.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £30, with board, lodging, and laundry.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence and washing.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Resident Obstetric Assistant for six months. Board and lodging provided.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary [illegible]

[illegible] laundry.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Two House Surgeons. Salary £80 per annum, with board, lodging, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

BASHFORD.—On June 4th, at 18, Downshire-hill, Hampstead, N.W., the wife of H. H. Bashford, M.D. Lond., of a daughter.

DENYER.—On May 30th, at Albion-street, Hull, Yorks, the wife of Stanley E. Denyer, C.M.G., M.D. Cantab., F.R.C.S. Eng., of a daughter.

GREENE.—On June 5t[illegible] Cheshunt, Herts, the wife of W. A. Greene, [illegible]

SPOOR.—On May 29t[illegible] Newington, London, the wife of Herbe[illegible] [illegible]in., M.P.S., of a son.

WILSON.—On June 5[illegible] the wife of J. Clark Wilson, M.D., M.[illegible]

MARRIAGES.

MILLER—WHITE.—On June 5th, at St. Mark's Church, Hamilton-terrace, by the Rev. H. C. Frith, Vicar of the Church of the Holy Redeemer, Clerkenwell, Reginald Miller, M.D., M.R.C.P., to Ethel, [illegible] White of Newton Abbot.

[illegible] parish church, Grantham, [illegible], M.B., to Dorothy Louisa, [illegible] Bousfield, M.A., Rector of [illegible]ld, Grantham.

[illegible] Church, Munich, by the resident chaplain, the Rev. D. Cooper Hunt, M.A., William McConnel, second son of the late Rev. Edward Wanklyn, Vicar of St. Michael's, Bournemouth, to Ethel, fourth daughter of the late Rev. C. H. Rice, Rector of Cheam.

[illegible], at the parish church, Croydon [illegible] Myrtle, youngest daughter of [illegible] Davidson.

DEATHS.

GATHERGOOD.—On Tuesday, June 1st, after a long illness patiently borne, Benjamin William Gathergood, M.D. (retired), at his residence, Aylmer Hall, Tilney, near King's Lynn, Norfolk, aged 57.

LEEDS.—On May 31st, at Mutrayfield, King's-road, Reading, Charles George Stretton Leeds, M.D., youngest son of the late Henry Leeds, Cheltenham.

[illegible] Samuel Thomson [illegible]

[illegible] Dorothy Skerritt, widow of the late Edward Markham Skerritt, M.D., F.R.C.P., of Ivor House, Durdham Park, Bristol, and eldest daughter of John Heelas of White Knight's Park, Reading, in her 60th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE BRITISH FIRE PREVENTION COMMITTEE.

THE occasion of the tenth anniversary of incorporation was celebrated recently by the British Fire Prevention Committee in various ways. A series of fire tests with fire-resisting doors was conducted at the committee's testing station at Regent's Park, and an anniversary banquet, *under the presidency of Mr. E. O. Sachs,* was held on May 25th at the Gaiety Restaurant.

The chief toast of "Success to the Committee" was given by the Earl of Londesborough, who pointed to the successful work done by the committee in reducing the loss of life and property from spread of fire, and who also dwelt on the greater knowledge of building materials and appliances obtained by the scientific and independent *tests at the committee's testing station,* which had done much to obtain a better understanding as to the value and also the limitations of the different methods of construction and equipment. He emphasised the fact that the committee's funds had been voluntarily raised and that during the ten years' work some £23,000 had been spent in research. About 150 subjects had already been under investigation, some of these involving as many as 20 or 30 testing *operations.*

The Chairman, in reply, indicated that the question of popularisation of fire prevention as affecting child life in particular would have the most serious consideration of the committee in the future, and that their efforts would be employed to combat the carelessness which resulted in children playing with fire, the dropping of matches in the street, and the use of celluloid combs and flannelette clothing.

[illegible] harmoniously to a common end.

A number of foreign delegates from the International Fire Service Council who were present spoke in appreciative *terms of the committee's* work of the last ten years. Many telegrams brought messages from abroad to the same effect.

The widespread acknowledgment of the research work and the reports of the British Fire Prevention Committee is well deserved, for it is a private body working voluntarily, whilst similar work [illegible] most terrible that in this country we are called upon to face. And there is too often a close parallel between the salvage which the fire brigade can effect in a burning house and that which the physician can bring about in a diseased body. The only satisfactory treatment for fire and disease alike is to prevent their occurrence, and in this endeavour the British Fire Prevention Committee is in honourable [illegible] research into the causes of the evils which they exist to combat. Anyone desiring further information of this interesting society will find its offices at 1, Waterloo-place, Pall Mall, S.W.

"RONTGEN RAY WRINKLES."

To the Editor of THE LANCET.

SIR,—I think Mr. Leslie Miller has chosen a singularly unfortunate title for his book—"Röntgen Ray Wrinkles." As Röntgen ray treatment is now so popular, not to say fashionable, for skin diseases such as eczema, the lay reader will be horrified to think wrinkles can be the result of this treatment!

I am, Sir, yours faithfully,

Park-street, W., June 6th, 1909. BERNARD E. POTTER.

THE LATEST QUACK ADVERTISEMENT.

THE gullibility of the public in all ranks of life as to anything concerning their health is well known. There is no form of "treatment," from "Christian Science" down to rheumatic rings, which is not believed in by someone. The United States are, however, the happy hunting ground of the quack, and the matter which we reproduce below will, we are sure, bring joy to the mind of Dr. Weir Mitchell as a story worthy of the delightful quack whose autobiography he wrote some few years ago.

Dr. Kaufmann, according to the circular which puffs his remedy, was in 1850 a professor at the University of Berlin, a post which he held for 13 years, during which time he is stated to have written *largely for* THE LANCET. *Concerning both these statements we* have considerable doubts. Among the numerous diseases which Kaufmann's Bitters will cure (according to himself) is "scrofula," and the letter which follows was written by a Mrs. Shaw, "a celebrated spiritualist and clairvoyant physician of West Twenty-Sixth-street, New York City." Mrs. Shaw, it will be noticed, does not give the year in which the *occurrence* took place.

(Copy)

New York City, August 1st.

My Dear Dr. Kaufmann,—Some time ago I treated a case of scrofula of over twenty-five years' standing, for which thousands of dollars had been paid without receiving any benefit. It came to my notice in [illegible] One evening while [illegible] fth Avenue, my attent[illegible] ho gathered was Mrs. ——, the wife of a wealthy banker of New Orleans, who [illegible] The [illegible] was [illegible] rious kinds had occurred, when, all of a sudden, rappings, screeches, and yells took place. In fact, it seemed as if a babble of noises had broken loose, when the bedroom door opened, and an empty bottle [illegible] one, until it was in front of this lady, who was troubled with the [illegible] then blew into the same lady's lap. It was afterwards examined and read by us all. I then persuaded the lady to try it. At this time she had suffered for twenty five years. Her case was the worst I ever saw. Her ears and eyes were in a most pitiable condition, and on her neck she had scrofulous lumps. And then for over six months she had suffered with running sores on her leg, and at this time her eyes were in such a condition that she could hardly see out of them, and her face was so bad that it almost made me shudder, as used as I am to look on the sick and suffering. Well, Doctor, to make a long story short, she took my advice and used your Sulphur Bitters, for when I saw those spirit manifestations take place that evening I knew Sulphur Bitters would cure [illegible] cured, [illegible] them [illegible] w me to say that I never saw the equal of your Sulphur Bitters in all diseases of the blood.

I am, yours sincerely,

EVANGELINE SHAW.

AN INFLUENTIAL APPEAL.

IN response to the appeal in THE LANCET of May 15th, the following further subscriptions have been received:—

PICTORIAL PRECEPTS FOR THE TUBERCULOUS.

WE have received a large sheet of highly picturesque illustrations showing what to do and what to avoid with a view to the prevention or limitation of tuberculous infection. Being well calculated to arouse popular interest, these pictures afford the most promising means of appealing to that section of the public which is in a general way impervious to advice on the subject of personal health. *The illustrations represent in a graphic manner the evils of indiscriminate spitting,* of intemperance, of constantly [illegible] and other hygienic errors. [illegible] supplied in three sizes, suitable respectively [illegible] hanging up, and as a handbill. We understand that the health com*mittee of Richmond,* in Surrey, is making use of these pictures for inculcating hygienic principles.

"METHODS OF BARBARISM" IN ITALIAN HOSPITALS.

IF anything could accelerate the reforms in the hospitals of Italy—reforms (writes an Italian correspondent) long engaging the attention of special commissioners and calling loudly for prompt and effective enforcement—it would be such an incident as the following, which has been going the round of the Roman press. A little girl, between seven and eight years of age, of respectable parentage, was recently *admitted* into the Policlinico for diphtheria and placed in the isolation pavilion. A "suora" (nun), with two "infermiere" (assistant nurses), was in charge of the ward. The little patient cried without ceasing, so audibly that the "suora," losing patience, seized her one evening, and with the aid of an "infermiera" dragged her to the dead-house, in which several corpses were lying. "If you don't keep quiet," was the "suora's" threat, "we'll leave you here among the dead bodies." The little girl, terrified out of her wits, "kept quiet" accordingly; but her parents, shortly thereafter, having come to know what had been done to her, lodged a complaint with the director of the Policlinico, who ordered the "suora" to be dismissed from the hospital. This is the last of a series of "irregularities" (to put it mildly) which, occurring in the best appointed and most "up to-date" of the Roman hospitals, has diffused something like a panic in the poorer classes, who (in the words of the official *Tribuna*) "tremble at the thought of their children having to go to the Policlinico." The dismissal of one of the clinical staff for moral turpitude; the "flirtations" (or worse) between patients and their visitors or attendants; the abandonment of the moribund by "suore" and "infermiere" alike; thefts of clothing and other articles belonging to the administration of the hospital; general disorder resulting from perfunctory surveillance—these and other sinister details to which the official journal calls attention in the week now passing more than justify the repugnance felt by the poorer classes to enter the Policlinico, or, indeed, the sister institutions whose record is not a whit more creditable. In an article on the whole question of the Policlinico and its management, the *Tribuna* draws attention (among many other abuses) to the pernicious system of "tipping" the nurses and inferior *personnel*. Inadequately paid, these functionaries graduate their services according to the "mance" (gratuities) they receive from the parents or relatives of the patients. "Hence," says the official journal, "the quarrels, the rivalries, the irregularities, in a word, the disorganisation of the service." The whole hospital system, indeed, not only in Rome but in the provinces, is more than ripe for reform, reform of the most drastic, the most "root-and-branch" description. Italy has many friends, nowhere so many or so free-handed as in the English-speaking world. But there are limits even to British-American loyalty and largess, and not a few among her sympathisers and supporters are beginning to echo the dying words of her life-long friend, Sir James Stansfeld, the coöperator and subsidiser of Mazzini and Garibaldi: "This Italy"—he used the words to Mde. White-Mario, as reported in the *Tribuna* some ten years ago—"is not the Italy you and I fought for!"

LYNN THOMAS AND SKYRME FUND.

THE following additional subscriptions to the above fund have been received: J. Harris Jones (Maesteg), £1 10*s.*; S. P. Francis (Brecon), 10*s.* 6*d.*

THE "HANDY" URINE COLLECTING BOTTLE.

IT is a matter of daily necessity to obtain samples of urine for purposes of analysis. The ordinary medicine bottle is not convenient for this purpose owing to its narrow neck. Messrs. C. J. Hewlett and Son, 35 to 42, Charlotte-street, London, E.C., have designed a new bottle in which the neck is extended in the shape of a funnel. It is convenient in shape, is secured by an indiarubber stopper, and enclosed in a neat japanned case. The bottle, which has a capacity of about four and a half ounces, can be easily cleansed and a roughened space is engraved on the front on which the name of the patient may be written. We have no doubt that this simple piece of apparatus will prove useful. The price is 2*s.* 6*d.*

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—Arthur Whitfield, E. G. Graham Little): at 5 P.M.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Situations wanted: First 30 words, 2*s.* 6*d.*; per additional 8 words, 6*d.*
Quarter Page, £1 10*s.* Half a Page, £2 15*s.* An Entire Page, £5 5*s.*

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnieres, Paris.

An Address

ON

A PROMINENT MOTIVE IN MURDER.

Delivered before the Medico-Legal Society on May 25th, 1909,

BY T. CLAYE SHAW, M.D. LOND., F.R.C.P. LOND.,

EMERITUS LECTURER ON PSYCHOLOGICAL MEDICINE AT ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—In obedience to the Censors of this society the title of the paper I have the honour of reading before you this evening—"On a Prominent Motive in Murder"—is, I fear, a tame one, calculated not to offend the susceptibilities of the most meticulous. Now that I am in possession of the rostrum you will, perhaps, kindly allow me to say that the subject I am bringing to your notice is the "lust for blood" as an incentive to murder, and inasmuch as I confess that the title does savour somewhat of the sensational I have coined a word, *hæmothymia*, which may I hope be allowed to pass muster and to do duty as a fit heading for a somewhat unlovely topic.

THE LUST FOR BLOOD—HÆMOTHYMIA.

I venture to hope that this subject may be deemed worthy of consideration by this society because there figures in many medico-legal cases the statement, which at times becomes an excuse, that with the sight of blood the desire or the impulse which caused the assault is satisfied; that an irresistible craving for blood prompted the agent to attack his selected, or in some instances indiscriminate, victims; and that this lust for blood—which prompts the name of "human tigers" for this class of persons—is to be held as an extenu [illegible] culpability of the prisone [illegible] objects of this society [illegible] conditions under which [illegible] *mmitted*, the presentation of this phase of emotional compulsion must be of interest if it leads us to a better comprehension of the conditions under which, terrible and repellent as they are, it occurs.

It is an unfortunate thing for a man when the emotional side of his mind leads him to commit crime—the intellectual side when it takes the form of delusion is fairly easily held to mitigate his responsibility; but however acute the mere feeling may be, however strong its compelling force, however morbid in its intensity, such a plea as "affective" or "emotional" insanity rarely, if ever, succeeds (unless to the allowance of extenuating circumstances) in procuring acceptance. And yet feeling and emotion are the chief sources, the well-springs, of action in life! *What is the poet or the painter or the musician without feeling or emotion?* What secures the upbringing of the infant, with its endless accompaniments of trouble and worry, but the emotional side of mind? The very sources of the fight for life, for food, for progress, for social safety are *essentially from the tapping of the emotional or affective* promptings. Indeed, will itself is so largely made up of emotional element that it is doubtful if it could exist without it; certainly, any preponderance or diminution in the intensity of the emotional part of the content of any state of willing must seriously *affect its validity*. If, *as experience* shows, there arise conditions or cravings which the sight of blood satisfies, we have to enquire into the nature of those conditions, whence they spring to such heights and with such force, and whether their existence is a morbid one.

There has always been an element of mystery about blood. From all time it has been bound up more than any other constituent of the body with life. Our earliest lessons from the Bible have held the flow of blood as the necessary indemnity for the remission of sin, and at the time of the Passover the sight of blood on the door-posts was the sign of protection from the destroying angel. It is the one constituent of the body forbidden by Mosaic law to be used as food. The very smell of it is peculiar, and to many is sickening, while many nursery rhymes and fairy tales are redolent of it, connotative of cruelty and revenge, and illustrating that the shedding of it is the last act of the fulfilment of a desperate purpose. Sir W. Thiselton-Dyer told me an incident which occurred during the time of Sir Mountstuart Grant Duff as Chief Commissioner in India. His Excellency had occasion to visit a native tribe in the outlying parts of Madras. As a visit from the Governor was a rare event much was made of it, and the natives gave him a most enthusiastic reception, in return for which the Governor promised to grant them, within his power, any particular favour desired in commemoration of his visit. The natives said that they had a statue of Agriculture which they wished to pacify inasmuch as their crops had for some time been bad. This pacification could only be effected by offering to the goddess the blood of a human victim, and they asked permission to be allowed, *just for once*, to celebrate the rite. They said that they had found that when the posts in front of the goddess's temple were smeared with blood the harvest was most abundant. *They had tried red sealing-wax on the lintels*, but found that it was of no use—the goddess was not to be taken in! From the very nature of its action, the guillotine had possibly more to do with the virulence and duration of the French Revolution than would have been the case if a bloodless method of execution had been used. The fury of the mob was undoubtedly increased and prolonged by the sight of blood, and when our bloodless executions were done in public the mental tone of the spectators was nothing compared with what was witnessed in our neighbours on similar occasions but with a different method. To those unaccustomed to the flowing of blood there is an emotional tone, induced partly by the sight, partly by the smell, and in part by the idea that life is in danger, and even to those accustomed to it a large hæmorrhage is always a matter involving anxiety and nervousness. I have noticed that surgeons whose operations are attended with much hæmorrhage, such as those on the tongue and throat, find the mental strain more than other classes of operators and sooner retire from their sphere.

Animals seem to associate life not so much with movement as with blood. They obey their tamer however much he may move about, but if he should happen to scratch himself and cause blood to flow, so that they see it and get the odour of it, there is no longer any safety for him. A man in the clutches of a wild animal may have a chance as long as he is perfectly still and has no wound, but the wild beast in quest of food knows that movement in its prospective prey means possible resistance and a potential fight, and therefore it may possibly attack a moving object, but if on the moving object there is blood then an attack becomes a certainty.

Young soldiers in action are said to be unnerved at the sight of blood, and for this reason it is said that the scarlet uniform was used either to conceal the colour of the blood as it flowed or to accustom the men to the colour of it. There is no doubt that the custom of "blooding the hounds" and the inauguration by "blooding" into the clubs of hunting men and women have the same object—viz., to render them familiar with the sight and smell of blood, to *baptise them into the corporate body*, and by creating a familiarity and a membership to elevate to *an ideal* to be grasped what might otherwise have acted as a forbidding sentiment. I cannot find that in early times savages celebrated this cult of blood in their young and *inexperienced men except* by public sacrifices, but in the absence of complete history I can quite understand that it would have been done. Modern warfare being more a matter of long range instead of hand-to-hand fighting must have modified the emotional element in that it has made the *men accustomed to the idea* that they are fighting without being paralysed or excited by the sight of blood—at any rate for some time after action has begun. It would seem that there are two objects in fighting—one to kill and the other merely to injure and incapacitate; hence nothing in the *former excites passion* so much as does the sight of blood, because it stimulates to fresh exertions in the same direction; whilst in the latter, where the object is merely to injure and not to kill, the sight of blood has a sobering effect, for it frightens the agent and shows that he has gone further than he intended. Where the object is to *kill* the sight of blood may also have a calming effect, because it shows that what was desired has been accomplished and that there is nothing more to be done.

What we want to know is the state of mind which, without *external provocation*, prompts to those murderous outrages which from time to time occur (e.g., the Jack the Ripper cases) in which no object can be seen beyond an apparently uncontrollable desire for blood. Here we note that there is probably an *emotional complex* present, not merely the desire for blood, but also an admixture with the love of notoriety, of a wish to frighten the public and of self-satisfaction at finding the prominence attained, the last acting as an incentive to repetition of the process to feed the flame of vanity. Ivan Bloch (p. 51), in talking of the biological and ethnological significance of the colour *red* in the sphere of sexuality, says that the nature of the sadist to "see red" is firmly founded on a physiological basis and merely exhibits an increase of a normal phenomenon. Hence many ingenious prostitutes wear a red chemise. He compares: "Lust, murder, and sadism, where women inflict slight injuries on their love partners for the purpose of sucking blood, which gives them sexual gratification (sexual vampirism)." The element of *cruelty* does not enter into the question in the same way as some may think. Modern writers on social psychology and emotion (Ribot and MacDougall) do not discuss the question of cruelty—they hardly ever mention the word—and yet in generally discussing acts of this class the word "cruelty" is much used—the agents are said to be "cruel" and "senseless." If "cruelty" means the needless infliction of pain (mental or bodily) just for the sake of it, then it does not appear that these people are cruel any more than we should call an animal cruel who kills another for food. The agent may indeed be the reverse of cruel in this sense, for it is not the horror of the torture chamber that he perpetuates and dwells upon, but the satisfaction of his own inordinate desire which he must gratify. A "cruel" man is, etymologically speaking, one who thirsts for blood (*cruor*) and the adjective "crudus" means full of blood; hence raw, uncooked, unfinished, as secondary meanings, but by the majority the real significance of the word is not appreciated.

Let us dive down to the early periods of human life to see whether we can obtain any illumination upon this lust for blood. Animals, especially the carnivora, which have to get their living, seem to be specially attracted by the smell of blood and the sight of it; it makes them furious to be placed under the influence of it (even the herbivora are specially affected by the smell of blood—e.g., witness the terror of cows cooped up near a slaughter-house). The sight of blood has long been associated with the death of the victim, and hence with the opportunity for the appeasing of hunger, and therefore, even if it be supposed to be a connate instinct, there is yet the powerful law of association remaining to make it a feeling, an emotion, a mover of the first rank. Without the feelings or emotions there is no stimulus to either impulsive or voluntary action, and this seems as far as we are at present able to go in the analysis of feeling. We do not know what it is nor how it is originally developed; we can merely note its existence and that there are degrees in its intensity We must just accept *this*, that the desire for blood is primarily a necessity for the means of living and that it may be the only way to satisfy a certain mental and bodily craving; it denotes the satisfaction of trends or tendencies to violence and destruction which, conscious or unconscious, exist in all men. As Ribot says (quoting Gall), the most violent tendency has its source in normal life. There is an inclination gradually rising from the pleasure of seeing anything killed to the most overpowering desire to kill. It is possible to pass by imperceptible gradations from the extreme case to the normal state in the following order: the pleasure of killing, the overpowering desire to kill, the pleasure of looking on at killing, the pleasure of seeing the blood of animals shed, the pleasure due to the representation of violent and bloodthirsty melodrama, and lastly, the pleasure of reading bloodthirsty novels or hearing accounts of murders, which is purely an affair of the imagination. If there is one psychological law more firmly established than another, both by facts and argument, it is that every intense representation—i e., idea—of an act tends to realise itself. How is it, he goes on, that artists who feel things violently never pass them into action? Because the law is in them subject not to an exception but to a *deviation* by the creation of a work of art which delivers them from the haunting idea. Morbid art is thus a defence against abnormal tendencies which otherwise would tend to transform themselves into action. Man being a carnivorous animal retains the trend of idea that the blood—in his acts of necessity and amusement—is the main thing—he must always be killing something, and with many the killing is the chief object of life. Hence big battues and other sport. Early men and savages, to whom cooking was unknown, ate the flesh raw and drank the blood of their victims, and there are now many who prefer meat raw or underdone. I remember that some years ago I had to examine the mental condition of one of the survivors of the *Mignonette*, the yacht which was wrecked, when some of the crew were exposed to the greatest hardships of hunger and thirst. They were reduced finally to killing the boy (who was almost dead before his veins were opened), and one of the participators in the carnal feast told me that he never experienced anything more delicious than drinking the blood—no doubt he was in the state to appreciate anything in the form of nutriment; but even the remembrance of his experience came back with a satisfaction which it is difficult to believe would have been so forcible with any other medium. Ribot talks of the emotions of elation and self-display as instincts, just as the desire for blood is primarily an instinct, and without doubt we see this instinct of self-display in animals, birds, and human beings. It may become a passion transcending prudence, as in the various excesses of dress and social functions, but being harmful to no one but the individual we take no notice of it, as we have done away with sumptuary laws. We expect these instincts to be confined within sober limits by the gradual growth of judgment; but when we find that judgment has not developed with a restraining force we are not surprised at the overgrowth of the instincts and at the infractions of the law which necessarily ensue. "Wisdom and blood combating in so tender a body we have ten proofs to one that blood hath the victory," says Leonato in *Much Ado about Nothing*.

Instances of the results of the overpowering mastery of the sexual instincts occurring in people of otherwise good judgment and of great intellectual power, of indulgence carrying them into compromising situations in spite of the knowledge that they are on dangerous ground, are common enough. The divorce court teems with such experiences. Craving does not wait on judgment, but writers on emotion and feeling shirk the definition of this pushing force. Of the various hypotheses perhaps the best is that which supposes craving to be the demand of the organism for something which is necessary for its continuance or its nutrition. This does not help us much if we do not know what the conditions are which call for this ministration of physical or psychic material. But it seems to be about as far as we can go. The difference between a food and a stimulant comes in here. Alcohol is an augmentor of energy but it is not a food. Ink-drinking supplies iron to the anæmic girl. The extraordinary tastes of pregnant women doubtless indicate chemical and nutritional needs, but what is the condition which calls for blood? It is a psychical craving due to a mental state which ordinarily has no force beyond being a sign that what is required for nutrition is in a condition ready for satisfying the craving, and it is a notable instance of the transference from the object to the subjective condition on which the objective rests for its accomplishment. Such transferences are not uncommon, witness how women buy things merely because they are tempted into shops or bazaars; they do not want them, they may have no use for them, but the mere *act of buying* must be satisfied because the idea of acquisition is so intensified that it becomes ideo-motor. A person at a great height throws himself from a platform, not because he *wants* to kill himself, but because the idea of throwing becomes ideo-motor; the man of the ideal trend does badly to keep firearms or poison in his possession because the fact of possession adds to the intensity of the idea, and the idea is very apt without wish or intention to expend itself in ideo-motor action. The paintings of realistic artists, such as Félicien Rops or Fragonard, the horrors of the Wiertz gallery at Brussels, the sensational murder stories of E. A. Poe are the fortunate motor outcome of strong ideas—fortunate for the authors, for the ideas, though offensive to many, are in reality the harmless outpourings of what might have been dangerous trends for their possessors. We shudder and say, "What a morbid mind such and such a person must have had," not recognising that we are gazing at the working out of an idea which might have had a very different ending but for the fortunate direction in which the overmastering idea resolved itself. The influence of the literature of the penny-dreadful order in arousing ideas of a kindred nature acting as incitements to theft and murder is an every-day experience, and the momentary enthusiasm of pageant or of scenic display is taken advantage of by the cognoscenti to ensnare people in obligations who are afterwards surprised at finding to what they have committed themselves.

The other evening a man near me in the gallery at the moment of the play, *An Englishman's Home*, when the Englishman is led off the stage to be shot, shouted out, "Cheer up, old chap; be a man, it'll soon be over!" If the recruiting sergeant had been near he would have found a ready conscript at the moment! How he would have liked it after his excitement had been dissipated is another question. An emotion once translated into action is impossible to recall: there is no further experience of it until the centres become charged again. Without doubt, much of this excess of feeling is morbid; it ought not in a properly balanced mind to arrive at such an intensity as to bear down restraint, and if it rises to such a pitch as to do more than is necessary for the need of the individual and his social system—i.e., if it shows itself incapable of modification by the means adopted by the environment—then measures must be taken by the predominant Social to check it. But our sociology takes little account of trends and tendencies until it sees what they result in, and this is perhaps inevitable. If we arrested every person who showed emotional excess because in some cases it *might* result in rape, murder, or larceny, we should deprive the world of inventions, of works of art, of philanthropy, and even of brilliant oratory and literature. So we accept the whole budget of possibilities with the risks incident to the admixture of harmless and dangerous tendencies. But in taking the risk we must not under-estimate the forces for evil underlying the volcanic crust of the social system. Perhaps we do not, after all, under-estimate these forces—we are surprised at nothing nowadays. We live in such inflammable elements that we note with cold blood what is done when the blood is hot, knowing all the time that "the brain may devize law for the blood, but a hot temper leaps over a cold decree." When we do get hold of the violator of laws we punish him with rigour, and I am inclined to think that there is less regard than formerly for mental infirmity, though the medical claims for the nature and extent of mental unsoundness, and therefore of lack of real responsibility, are much greater and sounder than they ever were. Doctors know that emotional excitement or exaggerated feeling is a morbid condition, often the prelude to delusional insanity; but whether going on to that or not it is a symptom of degeneration in many instances connected with a bad ancestry, and as such is entitled, if to punishment at all, at any rate to a modified punishment; but what chance would a delinquent have who, on the plea of a morbid desire for blood, claimed mitigation of penalty—and yet such a person might be more dangerously unsound than the man who, through his incoherence and delusions, gets off without any difficulty. The man who has inordinate cravings and dangerous trends or tendencies may complain that society has no right to allow him to go about as a free agent and then to avenge itself upon him when his acknowledged morbid trend forces him to deeds which he is unable to keep from. As a rule, we inflict a money tax on libertinism due to emotional *lâchetés*, the co-respondent is heavily fined, the man who commits an assault under angry or jealous feelings (perhaps mixed up with sexualism in some degree) is fined or perhaps imprisoned, the emotional suffragette is fined or sent to gaol, but the man who sheds blood can only pay for it in kind—that is the one law of the Old Testament which we exact, perhaps because we are ourselves so susceptible to feelings of horror on the mere suggestion of blood-spilling. If, then, to normal persons the idea of blood-spilling is so repugnant, what must be the state of mind of the person who finds his only satisfaction in taking the blood of innocent persons? And yet there are such people, and we allow them to go about in our midst while we calmly await catastrophes! The feeling of curiosity is often the basis from which cruel[illegible] There is something [illegible] horrible, and here i[illegible] pass into action of some kind. In the lower orders of society there are more emotion and more display of it than in the upper classes, and this partly because the latter have long been educated to conceal their feelings; there is not the actual stress of life which it is the object of emotion and feeling to alleviate, whereas the urgency of living in the former leads to those acts of violence which are so much more common in it than in other platforms of the social scale. People talk about the apathy and the sobering influence, the calmness, and the dry, intellectual judgment of the middle and upper ranks, it is the absence of *nécessité de vivre* which conditions this peaceful state, this agapemone of conflicting interests; but even here the element of the original lust of blood may be seen in the crowding of fair women to see the most dangerous jump in the steeplechase, in their presence at a sensational murder trial, or in their interested and eager contemplation of the writhings of the witness in the box under cross-examination in the Divorce Court. Very curious are the cases where the desire for the sight of blood prompts to suicidal attempts. I had under care a young lady who was suffering from an attack of adolescent insanity, during which she poured a canful of paraffin oil over her head and hands and then fired it with a match. She was badly burned and afterwards was much scarred. What surprised her was that at the time of the act she felt no pain, owing, of course, to the condition of anæsthesia which sometimes occurs in these cases, more especially in the cataleptoid forms. Being anxious to see if her power of sensation had returned she afterwards cut herself seriously in order to ascertain whether the blood flowed and to show that she was really alive.

As we get lower down in the social scale crimes of murder and violence are most frequent; there is plenty of vice and infraction of the law in the higher classes, but it is of a different type, and may be described as more of the intellectual life, forgery, swindling on a large scale, emotional excess of the selfish form. This may be due in part, as our President the learned judge once said here, to excess in drinking (especially of bad liquor) among the lower orders, but another reason is probably to be found in the lower state of evolution and in the degenerative surroundings under which they live, circumstances which naturally reinforce any trend or tendency to the uncontrolled instincts with which early life seems inseparably bound up.

Modern psychology, though it has done much to analyse mental processes, has not been up to now successful in enlightening us as to the real nature of the elementary processes themselves. It seems doubtful if we shall ever be much nearer than we now are towards a real comprehension of them, but we do at any rate know that there are actual facts or conditions, and, helped by pathology, we know that these conditions may be exaggerated or distorted in some whilst in others they never rise to any prominence—may, indeed, be scarcely existent. The law, which may be described as the verdict of the intellectual element of mind, as the declaration of what is the truth with the emotional element filtered out, ignores the validity of the chief side of mind out of which action oftenest arises; hence the lawyer and the physician must come into conflict, unless they come to terms about the primary psychological dictum—viz., that emotion or feeling is the basis of voluntary action, and that, therefore, any morbid alteration in kind or intensity of the form [illegible] with the

I [illegible] of hæmo-prog[illegible]-day, the thyr[illegible] appeal for the putting down of armaments, the enthusiasm of vegetarians, the demand for the commutation of death sentences, can be regarded as due to a process of evolution. We may be more slow to anger (experience has taught us the advantage of that); we may be more willing to pay when in older times we should have fought; we may be more careful of life; we may conduct wars on more humanitarian principles, but when once engaged the old emotions seem to come up in all intensity, and on occasion the call for blood overwhelms every other.

The result of all this is that whatever it may mean there is an innate primary feeling with regard to blood—at one time attractive, at another repellent, but in all cases strong. That trends or temperaments foster the one and increase the other; that the instinct is probably connected with the earliest efforts to procure food; that just as the sexual instinct or that of fear may be the direction of a trend and may be so strong as to lead to all kinds of extravagances (as we see daily that they do), so may the lust of blc [illegible] lead to murderous acts; that being [illegible] more compelling than most ideas, and as such should be correctly estimated; that as emotion or feeling is the primary determinant of our efforts to live, it should hold a prominent place in our estimate of responsibility, because any morbid elevation of it renders voluntary inhibition negative and such voluntary power as is caused must be in its own direction. It can only be repressed by eradication of the conditions by which it exists, and when once seen seclusion methods should at once be resorted to without waiting for the acts to which it must of necessity lead.

NOTE ON SOME OF THE THEORIES AS TO THE MODE OF PRODUCTION OF GROCCO'S PARAVERTEBRAL TRIANGLE OF DULNESS.

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN, ETC.

THE important paper contributed to THE LANCET of Dec. 5th, 1908, by Dr. Robert D. Keith and Dr. Arthur Keith on the Extension of a Pleural Effusion towards the Sound Side in a Still-born Child corresponding to Grocco's Paravertebral Triangle, had accidentally escaped my notice when it appeared. It deals so largely and with the weight of so much anatomical authority with the question as to the mechanism of that physical sign that it deserves the careful consideration of clinicians and particularly of teachers. In spite of the long interval which has elapsed, the following remarks may be still opportune as they do not appear to have been anticipated by any other published comments on the paper, and as they might yet elicit valuable criticisms from other quarters.

There are Paravertebral Dulnesses of Various Shapes and Origins, including that dulness which belongs to the bones and muscles of the back, and any dulness that may radiate across from a consolidation or a tumour. But there is only one of them which is of any use to us when our purpose is the detection of fluid—the "triangle" precisely as it is described by Grocco. Where opinions differ as to its presence the question arises as to the relative efficiency of the percussions themselves. As the dulness is *not a "dead dulness"* but a partial dulness only, the pleximeter undoubtedly gives an advantage to those trained in its use by yielding a much more definite note of dulness.

Had we no means available for discriminating between any spurious products of percussion and those that are genuine, and between *Grocco's triangle due to fluid* and any other paravertebral dulness not due to fluid, there would be a better excuse for confusions and for resulting doubts such as have recently found expression in THE LANCET, and as late as May 8th, 1909, in the *New York Medical Journal*, and which have delayed the general acceptance and use of a very simple and reliable method. That excuse ceased to exist after the publication in THE LANCET in 1905,[1] of the "*crucial test and counter test.*" If a dulness should disappear from the back on lying on one side and reappear on lying on the other side, it is not likely to be due to the bones and muscles of the back. Neither can it be the product of a pneumonic consolidation or of a tumour, unless we imagine that these can materially alter their relation to the chest wall (of course with due reservation for any pleuritic fluid bathing a pneumonia).

Apart from absolute scepticism as to its existence, the doubt which still prevails as to the cause of the phenomenon has been contributory to the delay. But the question has been thought not unworthy of the attention of anatomists, and among the best results of this prolonged discussion are those excellent contributions by Professor G. Elliot Smith of Cairo,[2] and by Dr. A. and Dr. R. Keith,[3] and the suggestions by Dr. F. W. Forbes-Ross,[4] all of whom recognise that the sign is a clinical one, though the cause be anatomical, and that any satisfactory explanation must rest equally on clinical and on anatomical evidence.

The Theories as to the Causation of the Triangular Dulness.—1. It may be convenient to attach the name of "the *Pleximetric-Spine Theory*" to that which is referred to by A. and R. Keith in the following terms: "Dr. William Ewart, who was the first in this country to explain the clinical signs of Grocco's triangle, ascribed it to the pleural effusion acting as a mute and preventing the vertebral column from conducting the pulmonary resonance."

Another view which they mention lies in reality outside the scope of the clinical question at issue, as it does not credit the effusion with the causation of the triangular dulness, but regards the latter as entirely physiological. "Dr. F. W. Forbes-Ross regards Grocco's triangle as a physical necessity of the anatomical conformation of the posterior chest wall; Roch and Dufour reach practically the same conclusion. Like Dr. Forbes-Ross they ascribe the triangle of dulness chiefly to the musculature of the back." The pleximetric spine theory is not critically analysed by the Keiths, but it is indirectly discountenanced by their approval of three other theories described in their valuable paper:—

2. *The Direct Fluid Dulness Theory.*—This is the old original theory which assumes a bulging of the water-logged pleural sac into the sound half of the chest sufficient to produce on percussion the paravertebral dulness.

3. *The Pulmonary Collapse Theory* will be presently discussed.

4. *The Posterior Mediastinal Mesentery Theory.*—This is the original and most important feature in their communication. It is set forth in the following words:—

> "The posterior mediastinal mesentery was described and figured by one of us in these pages some five years ago. It corresponds to the translucent triangle seen in the corresponding part of the thorax when the patient is examined in a suit[illegible] mesentery has been overlooked [illegible] hardened and always examined [illegible] and mediastinal contents are pressed backwards against the spine. It can be well demonstrated during the course of a post-mortem examination when the sternum and costal cartilages are removed. If the pericardium with its contents be then lifted forwards the posterior mediastinal mesentery will be seen to stretch from the pericardium to the spine and to have a front-to-back extent of from one to two inches. In our opinion Professor Elliot Smith is justified in applying the term [illegible] ll breath is [illegible] slack and long; it is its slacknes[illegible] and easy an extension of the con[illegible] side which has the higher ne[illegible] triangular in shape, apex above [illegible] when pressed into the sound side by a collection of fluid on the diseased side, thus giving rise to a triangle of dulness such as is described by Grocco."

The Direct Fluid Dulness Theory is best understood by glancing at their illustration (*loc. cit.*) based upon sections through the chest of a still-born infant in whom a *left pleural effusion* extended into the sound side, just as Professor Elliot Smith's illustration shows encroachment of a right pleural effusion into the left chest (*loc. cit.*)

> "It supports those who regard Grocco's paravertebral triangle of dulness as due to a direct extension of the pleural fluid or contents from the diseased towards the sound side. In Fig. A the contents of the thoracic cavity are exposed from behind. The left pleural cavity is distended by a pleural effusion, the left lung being compressed towards its [illegible] root, and the posterior mediastinal mese[illegible] mated leaflets of the right and left pleur[illegible] aorta, bulges towards the right so as to [illegible] lung. The extension of the posterior mediastinal mesentery [illegible] seen in the transverse section shown in B, *b*. The heart also is forced towards the right. …… Were such a chest to be percussed out an area of dulness to the right of the mid-line of the spine and corresponding to Grocco's triangle should be found."

The Pulmonary Collapse Theory seeks some support from the observation made by the present writer and appended to his original communication that an abscess below the diaphragm can give rise to a dull paravertebral triangle (which disappears immediately the abscess is evacuated).

> "Dr. Ewart believes that the fluid content of such an abscess acts, like a pleural effusion, as a mute on the spinal column. On theoretical grounds we should expect a subphrenic abscess to produce Grocco's triangle, but in a manner different from that supposed by Dr. Ewart. Recently Dr. W. Pasteur has dealt with "massive collapse" of the base of the lung as a sequence of subphrenic abscess and other abdominal inflammatory states; he ascribes, and we think rightly, the pulmonary collapse to a c[illegible] the diseased side, [illegible] tion. The do[illegible] raised upwards; there [illegible] of the elastic space on the diseased si[illegible] traction of the basal par[illegible] of the sound side there is the usual [illegible] sult that the collapsed basal part of th[illegible] drawn towards the sound side, giving rise to a triangular area of dulness."

[3] THE LANCET, Dec. 5th, 1908, p. 1699.
[4] THE LANCET, June 29th, 1907, p. 1773.

Any criticism of the foregoing views must be confined to the main points. In the matter of theories it may be said with every deference that "safety is *not* in numbers." Three theories should not be required to explain one plain fact. If differing, they suffer mutual defeat; if similar, then their agreement should be more absolute than it is in this case, to fit a quantity so strictly constant as the "triangle."

This constancy is the second consideration of a general *order which is to the point. Grocco's triangle was originally* introduced to us in terms of angles and of millimetres, its height alone undergoing variation; although the pleural *effusions vary extensively in bulk. Subsequently, however,* when I discovered in 1905 that it can also be produced by collections below the diaphragm, and in particular by ascites, I was able to point out that the base of the triangle was apt to be *broader in the abdominal cases.* In short, it may be said of all three theories that they agree neither among themselves nor with the mathematical feature of the phenomenon they ought to explain.

Passing now to details, a principle of fundamental importance to clinicians in their study of intra-pleural events is the fact that a lung laterally compressed by fluid retreats into the spinal groove by virtue of the posterior position of the pulmonary root above and of the attachment below of the *posterior edge of the lung by means of the ligamentum latum* pulmonis. This recession and this attachment have always seemed to me to govern in effusion the persistence of the spinal and vertebral resonance for some distance below the upper level of the fluid, and the production of the S-shaped outline of dulness of Damoiseau, and they must not be lost sight of in the present connexion. In upward compressions from abdominal lifting of the diaphragm the same principle should hold good; and it is not easy to realise how the posterior pulmonary border could possibly vacate its groove.

Another principle is that whatever may happen to the anterior pulmonary border by way of collapse or of enlargement or of *encroachment into the other half of the thorax,* the pulmonary *root and a fortiori the posterior border are* incapable of any migration across the vertebral column. This is precluded by the attachments of the centrum tendineum to the spine on the one hand, and to the inferior vena cava on the other. The posterior and vertical axis of rotation of the heart which passes through the foramen pro vena cava from the liver up to the superior vena cava and the innominate artery may be stretched in its upper part, and lower down it may sway slightly with the centrum tendineum and with the liver under the stress of powerful pressures, as in Professor Elliot Smith's case. But this lateral displacement can amount only to very little, and the close connexion of the spinal column with the pericardium and the posterior mediastinum, *kept up through the vena azygos, raises* an impassable barrier between the two spinal grooves, precluding any transference of viscera from the one into the other.

There is, moreover, a new clinical fact which seems to leave little standing ground for any theory dependent upon alleged oscillations of fluids or of viscera across the middle line. I have more recently realised that a Grocco's triangle can be percussed out *on both sides of the spine in bilateral pleural effusions,* as well as in ascites. This is easily demonstrated by the skilful use of Sansom's pleximeter. The significance of this fact from the point of mechanism *is obvious. The two triangles could not be produced* by reciprocal encroachment by bulgings, but they can be explained as the result of reciprocal percussion waves. A pleximetric conduction would also seem to be the only explanation available for the telling fact that the two triangles are almost always *of uneven height* as the two effusions are rarely equal.

The conclusions may be briefly stated :—

1. Grocco's paravertebral thoracic triangle of dulness, due to fluid free in the pleura, is *rectilinear not curved;* and in other respects also it agrees with the description of it given by Grocco.
2. It is also produced by fluid collections in the abdomen; its base is then *broader* than in pleural cases.
3. In the latter neither its width nor its shape vary appreciably, but only its height; this rises exactly to the level reached by the effusion itself.
4. *In bilateral cases* of pleural effusion a Grocco's triangle can be made out *on both sides,* in spite of the dulnesses due to the two effusions. As the effusions are seldom quite equal two unequal Grocco's triangles are the rule.
5. *In ascites* and analogous abdominal cases the rule is for the two triangles to be equal; they therefore make up together a low but wide equilateral triangle bisected by the spine.
6. The simultaneous occurrence of a right and of a left Grocco's triangle is incompatible with the alleged causation by *pleural bulging* across the vertebral column.
7. The same reasoning applies to the theory that a *pendulum displacement* of the intra-thoracic viscera across the middle line might explain the dulness.
8. Anatomical probabilities are against any possible shifting of a *collapsed pulmonary base* away from its own *vertebral groove.*
9. The assumption that a Grocco's triangle is produced *directly* by any fluid or other non-resonant substance immediately *underlying it is negatived by the circumstance that* the general outline of the triangle is always "geometrically" the same and is not contingent upon the innumerable variations in size and in shape which *belong to fluid collections* or to solidifications.
10. This is an argument in favour of the causation suggested under the name of the *pleximetric spine theory.*
11. The same view is supported by the results of the *crucial test and counter test,* which also afford proof of the genuineness of this clinical sign and of its helpfulness in the diagnosis of pleural and abdominal conditions.

Upper Brook-street, W.

PANCREATIC GLYCOSURIA TEN YEARS AFTER TYPHOID FEVER.

BY P. J. CAMMIDGE, M.D. LOND.

ON Sept. 8th, 1908, I was consulted by an American gentleman, who came to me with a letter of introduction from Dr. J. B. Murphy of Chicago. In his letter Dr. Murphy stated that the patient was suffering from diabetes and had been sent to me with the object of determining the condition of his pancreas and clearing up the etiology of the disease. He also informed me that there was a distinct history of cholecystitic infection.

The patient was a well-built, healthy looking man, 51 years of age. He had had no serious illness, except an attack of typhoid fever in 1898. There was no history of [illegible] gastro-intestinal disturbances, nor had he had any [illegible] -stones. Although [illegible] o alcohol. He had [illegible] The quantity of urine excreted had not increased. So far as he knew he had not lost flesh, nor had he noticed any diminution of strength. 3 per cent. of sugar had been found in his urine in the course of a routine examination at an American health resort in January, 1908, but on an anti-diabetic diet this had been reduced to about half.

A physical examination revealed nothing abnormal. The patient's tongue was not red or glazed, and his gums and mouth appeared normal. His skin was moist. His heart was not enlarged, the heart sounds were natural, and his arteries were not thickened. His abdomen and body generally were well covered with fat. No abdominal tumour or swelling could be discovered on palpation. The liver dulness was normal and the stomach did not appear to be dilated. Analysis of a specimen of the mixed night and morning urine gave the following results :—

[illegible] 1023; albumin, about 1 : 5000; sugar, [illegible] lhydrazin, crowds of [illegible] 33 per cent. sulphuric [illegible] luction (Bang's method). [illegible] stein's [illegible] nil; indican, a fairly well n[illegible] logical excess; blood, nil; [illegible] °C. [illegible] of a dextro-

The urine, therefore, [illegible] rotatory fermentable su[illegible] variety. The results of [illegible] that the glycosuria was [illegible] the pancreas, and the presence of many small calcium oxalate crystals in the centrifugalised deposit tended to confirm this conclusion. The pathological excess of urobilin pointed to there being a catarrhal condition of the biliary passages, which probably extended to the pancreatic ducts. The abnormal reaction for indican and the disturbed relation of the preformed to the conjugated sulphates suggested that both the pancreatic disease and cholangitis were connected with a catarrhal condition of the upper part of the intestinal tract. The absence of any trace of acetone or aceto-acetic acid showed that there were not the profound tissue changes met with in severe diabetes and rendered it probable that the pancreatic disease was of a slowly advancing type, such as, in my experience, is the common result of cirrhosis of the pancreas secondary to infection of the ducts. Although the specimen contained traces of albumin, the fairly normal critical solution point, the normal percentages of urea and inorganic salts, and the absence of casts or other evidence of renal mischief rendered it unlikely that there was any serious disease of the kidneys, while the presence of leucocytes and transitional epithelium suggested that it was not improbably of bladder origin.

The bowels were stated to be opened regularly every day, and there was neither diarrhœa nor constipation. A sample of the fæces submitted for examination gave the following results:—

[illegible], solid mass; reaction, amphoteric; [illegible] occult blood, *nil*. Microscopically, [illegible]rtly digested muscle fibres, some [illegible]globules;

Organic matter	86·7%	of the dry weight, normal	85–89%
Total fat...	16·6%	" " "	15–25%
Unsaponified fat...	8 6%	" " "	10–15%
Saponified fat	8·0%	" " "	10–15%
Organic matter not fat ...	70·1%	" " "	60–75%
Inorganic ash	13·8%	" " "	10–15%

The only striking variation from the normal was the large amount of partly digested muscle fibre found microscopically, but this was probably to be explained by the highly nitrogenous diet which the patient was taking. There was no marked excess of unabsorbed fat, nor was the relation between the saponified and unsaponified fats disturbed in the way that one might expect in serious disease of the pancreas. This, however, I have found in a considerable number of cases of glycosuria of undoubted pancreatic origin in which I have had the opportunity of examining the stools, and I have come to the conclusion that any marked interference with fat digestion is of serious prognostic significance and indicates that the patient is in the last stages of the disease. The absence of any trace of occult blood was against there being any malignant growth in the course of the gastro-intestinal tract, to which the pancreatic disease might be secondary.

As I have pointed out elsewhere,[1] I have been led to divide cases of pancreatic diabetes into three classes, according to the probable origin of the pancreatic affection:—(1) Those in which the morbid influence has reached the gland by way of the ducts; (2) those secondary to blood diseases or circulatory disturbances; and (3) those in which the diabetes has been induced by destruction of the pancreas by malignant growths. There was no evidence that the case under consideration fell under either the second or third head, while the urinary analysis suggested that it was associated with an infection of the pancreatic ducts and biliary passages.

Bearing in mind the history of typhoid fever, and the now well-recognised tendency of the typhoid bacillus to linger in the gall-bladder and bile-ducts, in some cases, long after the patient has quite recovered from the disease, it seemed to me possible that I had to do with a case of typhoidal pancreatitis going on to glycosuria, and that a bacteriological analysis of the fæces might throw further light on the condition. A portion of the fæcal material was taken with a sterile knife from the centre of the mass sent for examination, emulsified in sterile normal saline solution, plated on Drigalski and Conradi's medium, and incubated at 37° C. On being examined 24 hours later one of the six plates that had been inoculated showed two small, blue, finely granular colonies, with raised centres and filmy edges, suggesting bacillus typhosus. Sub-cultures were made from these on to agar-agar slopes and incubated at 37° C. for 24 hours; they then showed a thin, bluish-white, translucent film, that had not spread far from the needle track. Hanging-drop preparations showed actively motile rod-shaped bacilli. The bacilli did not stain by Gram's method, and cover-glass preparations stained by Van Ermengen's method showed that they were richly flagellate. Glucose-gelatine shake cultures showed no gas formation in 48 hours. Lactose litmus broth was not rendered acid and showed no gas formation. Litmus-milk cultures were not coagulated, nor was there any acid formation in 48 hours. Neutral red broth became turbid, but there was no film formation or colour change. Peptone salt cultures incubated at 37° C. for 48 hours gave no indol reaction. An emulsion of the bacilli in normal saline solution, prepared from a 24 hours agar culture, gave a similar reaction with a typhoid serum to a laboratory culture of bacillus typhosus. The fæces, therefore, contained a small number of bacilli having the appearance and characters of bacillus typhosus; a result which tended to confirm my surmise as to the probable origin of the disease.

Pancreatitis is not a common sequel of typhoid fever, and as yet there has been no reported instance in which glycosuria has developed as a result of typhoidal infection of the pancreas. The interval of ten years that had elapsed in this case between the original infection and the discovery of sugar in the urine, at first sight, made it a little difficult to believe that there could be any etiological relation between the two, but as the bacteriological examination of the stools showed that typhoid bacilli were still present, and there was evidence pointing to a focus of infection in the biliary passages and pancreatic ducts, it was not too much to assume that such a relation existed, and that the glycosuria was the direct outcome of slowly advancing changes in the pancreas set up by the persistent infection. Contrary to what has been generally taught, I have found that pancreatic diabetes is usually a mild and slowly advancing disease, often unattended by any marked symptoms for many years,[2] so that the absence of any physical signs and the latent character of the disease in this case did not surprise me but rather tended to confirm my view as to the cause of the glycosuria.

In the treatment of pancreatic diabetes it is essential to first determine the cause of the condition of the pancreas and endeavour so far as possible to control it. As it was highly probable that in this case the primary etiological factor was an infection of the pancreatic ducts and biliary system with typhoid bacilli advantage was taken of the results of the experiments by S. J. Crowe,[3] in which it was shown that hexamethylenetetramine (urotropine) given by the mouth to dogs is excreted in the bile and pancreatic juice in quantity and speedily sterilises the ducts that have been artificially infected with typhoid bacilli. Ten grains of this drug, with ten grains of sodium salicylate, which is also excreted in the bile and pancreatic juice, were therefore ordered to be taken three times a day in two ounces of water for three weeks, when it was suggested that the fæces and urine should be again examined. The second indication for treatment is to discover the patient's tolerance and powers of digestion for the various forms of sugar (particularly levulose and dextrose), starch, fat, and proteid, so that a diet may be arranged which, while it throws a minimum amount of work upon the pancreas and combats the glycosuria, may yet supply a sufficient quantity of nourishment to keep the patient in good condition. The only really satisfactory way of arriving at such a diet is to have the patient under observation in a nursing home or hospital for a short time so that the food may be accurately prescribed in weighed quantities and the effects of variations, with and without the addition of preparations of pancreas, can be determined by regular quantitative analyses of the urine and fæces. Such a procedure also has the advantage of educating the patient to a new mode of life and placing him in a much better position to take care of himself subsequently.

As this patient was obliged to return to America immediately after I had seen him I was only able to give him general directions as to his diet and mode of life, based upon my experience of similar cases, and suggest that he should consult his medical adviser in Chicago and get him to work out a diet chart suitable to his needs.

THE RELATION OF ACIDOSIS TO THE CARBON DIOXIDE OF THE BLOOD IN DIABETIC COMA.

BY A. P. BEDDARD, M.A., M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL; PHYSICIAN, WEST LONDON HOSPITAL;
M. S. PEMBREY, M.A., M.D. OXON.,
LECTURER IN PHYSIOLOGY AT GUY'S HOSPITAL;
AND
E. I. SPRIGGS, M.D. LOND., F.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN, ST. GEORGE'S HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

Dr. Pavy, in his lectures on the Pathology and Treatment of Diabetes Mellitus, criticised at some length, and adversely, the conclusions we had drawn from our observations on diabetic coma. He has brought forward no new facts and does not deny the accuracy of our observations, but disagrees with the view to which a consideration of the experiments made by ourselves and other workers has led us. The facts that are not in dispute may be briefly summarised as follows. Directly coma sets in the patient shows a well-marked hyperpnœa. The "alkalinity" of the blood—that is, its power of combining with acids—is reduced, and the [illegible] patient's blood is materially [illegible] such as sodium bicarbonate [illegible] injected into a vein the "alkalinity" of the blood and its carbon-dioxide content are increased, and the symptoms of coma may disappear, at least temporarily. When coma is imminent the patient's appetite becomes extremely poor, and during coma the metabolism of the body, as judged by the output of dextrose, nitrogen, and carbon dioxide, is greatly decreased.

The interpretation of these fundamental facts on which *Dr. Pavy insists is that which has been given by the majority* of observers ever since the classical experiments of Walter on the poisoning of animals by acids. According to this view, the prolonged acidosis of diabetes reduces the amount of base which is available in the blood and tissue fluids for combination with carbon dioxide; the blood therefore contains less carbon dioxide, and being unable to transport as much as should be removed from the tissues carbon dioxide begins to accumulate in them. In the case of the respiratory centre carbon dioxide is its normal stimulus, and, therefore, the centre is, at first, stimulated to greater activity. The accumulation, however, of carbon dioxide leads to a cessation of its production; and, as Dr. Pavy says, "death takes place when the non-removal has attained a sufficient height to reduce the occurrence of activity to a point which is no longer consistent with the continuance of life."

It is possible to draw from this view certain deductions which can be tested experimentally.

In the first place, so long as the body is alive it will continue to produce carbon dioxide. Whenever the blood is unable to remove it as fast as it is produced, carbon dioxide must accumulate in the tissues, and if it accumulates then its tension in the tissues must be raised; both of these deductions are *apparently admitted by Dr. Pavy.* Unfortunately, there is no method of estimating directly the carbon dioxide tension in the tissues; but it is generally assumed that the tension of carbon dioxide in the renal cells would not be raised without that in the urine being correspondingly increased. *We have shown that the tension of carbon dioxide* in the urine in diabetic coma is not raised.

In the second place, if the "alkalinity" of the blood begins to fall, and if carbon dioxide begins to accumulate at an increased tension in the tissues, the blood in the capillaries must be exposed to an increased tension of carbon dioxide. And although the reduced "alkalinity" of the blood might prevent its taking up a normal quantity of carbon dioxide, nevertheless such gas as the blood did take up would be under an *increased tension. The tension of the carbon dioxide in the blood can be either estimated directly* or deduced from an analysis of the alveolar air. By the former method we have found that it is at any rate not increased, and by the latter that it is, as a matter of fact, diminished even to a fifth of its normal value, and that this decrease is *greatest during coma, but is obvious for days both before and* after the coma.

In the third place, Dr. Pavy points out that if an alkali is injected into the blood the symptoms of coma cease temporarily; and this he explains by saying that the alkali has increased the power of the blood to combine with carbon dioxide. If this explanation of the good effect of alkali *were true, then, since the blood in the capillaries would* be exposed to carbon dioxide in quantities greater than it is capable of taking up, and at a tension above the normal, the venous blood, in addition to containing carbon dioxide at a tension above the normal, should be saturated with carbon dioxide for that abnormal tension. We have shown by direct experiment not only that the tension is not raised but that the blood is not saturated even for a tension of carbon dioxide below the normal. Further, if the arm of a *patient is bandaged for a sufficiently long time—such, for* instance, as two minutes—before the blood is drawn, the *carbon-dioxide content of the blood can be raised even* up to the normal. In fact, the blood in coma and the precomatose state can combine with very much more carbon dioxide than it actually contains, as will be seen by reference to our determinations.

These observations render untenable the view which is still advocated by Dr. Pavy, and which we ourselves held *until we began to work at the subject.* This view is based upon the assumption that the decrease of carbon dioxide in the blood is primarily due to the inability of the blood to combine with more carbon dioxide than it is found to contain. This we have shown to be untrue. Some other explanation of the fundamental facts of diabetic coma is necessary, and this we have already attempted to give.

Blood is both alkaline and acid in the sense that it can combine with acids and alkalies. Physico-chemical investigations upon the relative concentrations of acid and basic ions in blood show that in health its reaction is always roughly neutral, approaching that of distilled water. Strictly speaking, the reaction of blood is alkaline to such a slight degree that it may be referred to as being neutral. The *reaction of lymph, tissue-fluids, and protoplasm is presumed* to be the same as that of the blood. It is probable that the slightest disturbance of this chemical neutrality affects the metabolic activity of protoplasm, and that but a very little upset of the neutrality towards the acid side is incompatible with life. During metabolism carbon dioxide and other acids are continuously produced. In the case of distilled water, the least addition of carbon dioxide or other acid destroys its neutral reaction, but in the case of blood and protoplasm, owing to their carbonates, phosphates, and proteins, considerable quantities of carbon dioxide and other weak acids can be added without altering their reaction and destroying their neutrality. This power of the blood and protoplasm to combine with acids without change of chemical reaction has been *called by B. Moore "reactivity" to acids.*

During the prolonged and severe acidosis of diabetes the bases become combined with abnormal acids, and are no longer available to combine with the normal acid products of [illegible] "reactivity" to acids of the [illegible] On this account during [illegible] body would be imperilled [illegible] own metabolic products. The cells would be less capable of withstanding the acid *properties of their metabolites and would become more* sen[illegible]tion of all acid substances. In [illegible] the quantity and tension of car[illegible] progressively reduced, not, as we have shown, because the blood cannot take up more carbon *dioxide than it is found to contain*, but because the rising concentration of acid ions in the blood and protoplasm progressively affects the activities of cells. It has been shown by many observers that the quantity of carbon dioxide in blood under comparable conditions of experiment runs parallel with and may be taken practically as a measure of the power of the blood to neutralise acids. As the power of neutralising acid substances manufactured during metabolism progressively falls tissue activity correspondingly decreases, and less carbon dioxide and other acid substances are produced. Also, the respiratory centre is stimulated to greater activity and the hyperpnœa pumps carbon dioxide out of the blood. We have shown that the diminution of carbon dioxide in the blood is present for days before coma begins and lasts for *days after coma* has passed off. During coma this change is associated with a great increase of the total pulmonary ventilation and a great fall of the carbon dioxide in the alveolar air. We have suggested that the extreme diminution of the carbon dioxide in the blood in coma is in part due to the rapid removal of carbon dioxide by the hyperpnœa, an explanation which Dr. Pavy accepts. Before coma begins and after it has passed off there is still present a marked fall of carbon dioxide in the blood and alveolar air, but it is less in degree than in coma. Further, it may be present when the total pulmonary ventilation is low and cannot therefore be due to an excessive pumping of carbon dioxide out of the body. When such a patient is made to hold his breath, he is not able to stop breathing sufficiently long to raise the percentage of carbon dioxide in his alveolar air to the normal—that is, his respiratory centre owing to the acidosis reacts more readily to carbon dioxide. If he is given oxygen to breathe containing a percentage of carbon dioxide 2·5 per cent. greater than that in his alveolar air, he absorbs the carbon dioxide from the mixture into his blood. We conclude, therefore, that the low percentage of carbon dioxide in the patient's blood and alveolar air is due not to his blood being unable to take up more than it was found to contain, but to a diminished production of carbon dioxide by his tissues and to an increased sensitiveness of his respiratory centre to carbon dioxide.

We have, therefore, shown that in the precomatose and comatose states of diabetes the blood can take up more carbon dioxide than it contains and that there is not an accumulation of carbon dioxide in the tissues. Failing any other explanation, we conclude that the diminution of carbon dioxide in the blood is caused by a decreased production and by the hyperpnœa when present, and that both are alike caused by the acidosis. It is necessary to explain the onset of the hyperpnœa. Haldane and Priestley and others have shown that in health carbon dioxide is the chief stimulus to the respiratory centre. In diabetic coma, hyperpnœa begins and continues although the quantity and tension of carbon dioxide in the blood are low and there is no accumulation of carbon dioxide in the tissues. At first sight it is not obvious how in this case carbon dioxide could be an effective stimulus to the centre. If carbon dioxide could affect the centre only in virtue of a specific chemical action it could not be the stimulus in coma. We have shown that in diabetic coma the respiratory centre is not stimulated to greater activity, as it is in health, by a slight increase of carbon dioxide in the blood. A patient in coma was given air to breathe containing 2·6 per cent. more carbon dioxide than was in his alveolar air and the hyperpnœa was not increased. The same patient, three days' later, when he was conscious and his hyperpnœa had disappeared, was again given air to breathe containing 2·6 per cent. more carbon dioxide than was in his alveolar air, and his hyperpnœa returned at once. Carbon dioxide is also an acid substance, and although it may be the principal, it is by no means the only, acid substance produced even in normal metabolism, much less in severe diabetes. We therefore put forward the view that the effective stimulus to the respiratory centre in coma was the increasing concentration of unneutralised acid substances. Our view was expressed in these sentences: "It is suggested that the following process is taking place in the nerve cells of the medulla. The decreased 'reactivity' of the protoplasm of the cells due to the prolonged acidosis renders their reaction more easily disturbed by, and therefore makes them more sensitive to, the stimulating influence of any acid body, including carbon dioxide and other acids produced during metabolism." When criticising this view Dr. Pavy quotes against us the work of Haldane and Priestley, which indicates that in health the activity of the respiratory centre varies directly with the tension of carbon dioxide in the blood. Dr. Pavy therefore calls our explanation of the hyperpnœa in diabetic coma "vague, unsubstantiated, and extraneous." When Dr. Pavy wrote this criticism he was apparently unaware that Haldane, like other observers, had already maintained that carbon dioxide is not the only substance which stimulates the respiratory centre, and that in order to explain the regulation of respiration it is necessary to believe that even in health acid bodies other than carbon dioxide do stimulate the centre. This view was put forward originally by Pflüger, Geppert, and Zuntz, and has been amply confirmed by the recent work of Haldane, Pembrey, and others. In fact, our view of the cause of the hyperpnœa in coma is in strict accord with what is known of the regulation of respiration in health, and with the changes which take place in the body in severe diabetes. Similar changes will be taking place in all the other cells of the body, and we imagine that as the acidosis increases the metabolic activity of the tissues is thereby slowly and progressively diminished until consciousness, and finally life, is no longer possible.

Dr. Pavy in his lectures reaches several conclusions in regard to diabetes in general from which we strongly dissent. But we defer a consideration of the subject until the publication of our observations on diabetic patients, when we propose to raise the points in question.

ON THE OPERATION OF CARDIOLYSIS: ILLUSTRATED BY A CASE.[1]

BY F. J. POYNTON, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, ETC.;
AND
W. TROTTER, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ETC.

THE operation of cardiolysis was first suggested in 1902 by Brauer and put in practice by Petersen—two names which to-day are associated with another and much more important advance in the surgery of the chest. The name cardiolysis is perhaps a little misleading, as it is at any rate more impressive than the surgically simple procedure to which it is given. It was pointed out by Brauer that in certain cases of adherent pericardium where the heart is embarrassed by fixation to the surrounding parts, a considerable amount of this overloading of the heart's action could be got rid of by rendering the præcordial part of the chest wall more flexible than normal by removing its bony and cartilaginous framework. No extensive separation of adhesions was suggested, and it is obvious that under the circumstances in which the operation has to be done such procedure would be very dangerous. In the first place the circulatory conditions are very unfavourable for prolonged general anæsthesia, while the risk of tearing the left pleura or even the heart wall would seem to be very great. The suggestion of Brauer was therefore *prima facie* an excellent one, and it obtained immediate practical justification in the operations done on his cases. The operation was extremely simple and short and the results were encouraging. Nevertheless, it seems to have been very little done. A review of the subject published in August, 1908, by Ernst Venus[2] gives a total of 17 cases, three of them being Braner's. The article contains a summary of all the cases and seems to be founded on a very complete study of the literature. There is no death recorded as the consequence of the operation, and the results appear on the whole to be very good.

In regard to the indications for operation there is a fairly general agreement amongst the various authors that those cases only are suitable in which the heart has shown some capacity for recovery under treatment by rest in bed. Clearly, if relief of the overloading of the heart is to be obtained by mobilisation of the præcordium, the capacity of the heart to recover must be demonstrable when the overloading is relieved by rest. It would seem then that the most suitable cases are those in which the heart is just inadequate for active life.

In all the published cases general anæsthesia seems to have been used, on the whole without much trouble. The operation need not last more than a few minutes and no very profound degree of anæsthesia is necessary, so that if the patient has been kept at rest for some time previously there seems no great objection to the use of chloroform. If it were necessary, however, to do the operation at a time when the heart was in an unsatisfactory condition there can be little doubt that a local anæsthetic should be preferred. As is well known, the chest wall can be very satisfactorily infiltrated with cocaine and adrenalin, and one has been able, for example, to open the pericardium very freely under it in a child with purulent pericarditis without causing pain.

---

[1] A paper read before the Clinical Section of the Royal Society of Medicine on May 14th, 1909.

[2] Centralblatt fur die Grenzgebiete, Band xi., No. 14.

The technical details of the operation are very simple. A horseshoe-shaped flap should be marked out having its base above at the third rib and its apex at the seventh. The inner edge should be over the sternum and the outer in the region of the nipple line. The flap is turned up with the pectoralis and all the structures external to the ribs. The fourth and fifth ribs are those most commonly excised, but the extent of the rib resection will, of course, depend on what is found. A length of at least 3 or 4 inches of combined rib and cartilage must be removed. The third, the sixth, and even the seventh rib must also be dealt with if it appears necessary, and even the left edge of the sternum has been excised when the heart was obviously fixed to it.

There has been but one subject of disagreement in the matter of technique, and that is the question of the removal of the costal periosteum. Küttner, Danielsen, Leukenbach, and von Beck all insist on the importance of removing the whole periosteum of the resected ribs lest the mobilised part of the chest wall become rigid again. König, however, points out that this is extremely difficult to do, and has, in addition to the general disadvantage of prolonging the operation under circumstances where saving of time is very important, the special disadvantage that there is considerable risk of a wound being made in the left pleura. The latter, as is now well known, comes inwards normally as far as the left edge of the sternum and is by no means necessarily obliterated in these cases. He recommends, therefore, that the anterior periosteum only should be removed. That this is the proper course to follow and is not likely to lead to re-ossification is shown by a number of cases in which the præcordium has remained flexible for a long period, and especially by a case of König's, in which, two and a half years after the operation, the patient having died from general tuberculosis, a necropsy was made. It was shown that practically no ossification had occurred. The possibility of leaving the periosteum without damaging the usefulness of the treatment makes the operation still more simple and removes the only serious risk it could be supposed to have.

In the case reported at the end of this paper the fourth and fifth ribs were removed for a length of about 4 inches in front of the heart, the periosteum being left behind. The latter was obviously adherent to the front of the pericardium and pleura, and the extent to which it was drawn in and out by the tumultuously beating heart gave one a very clear idea as to how much the cardiac movements must have been hampered by the rigid chest wall.

So far as the general condition of our patient was concerned, he appeared to be a favourable case. He improved greatly with complete rest, but was quite unable to cope with exertion of the most ordinary kind. His general health and development were good, and his disposition was cheerful. There was no valvular lesion, and there were striking indications of mechanical embarrassment. Nevertheless, we felt then, as we feel now, that it is in reality a very difficult matter to gauge the condition of the myocardium. His improvement has been slow and we do not bring him forward as an example of a complete cure, far from it, but he is undoubtedly in a much better condition than he was, and we hope that with continued care he has not yet reached the limit of his progress. We would emphasise in particular the great improvement in the force and volume of his pulse and the diminution in the size of the spleen and liver and the degree of dropsy. On the other hand, it must be pointed out that the cantering cardiac rhythm is still present and the action irritable, as it is in some cases of "soldier's heart." We believe that the choice of suitable cases is not easy, and would in particular look with suspicion upon cases of multiple serositis in which there may be, so far as the heart is concerned, indication for this operation, but which from their tendency to show exacerbations and to spread from serous membrane to serous membrane, would probably not be favourably influenced by surgical interference.

The patient, a male, aged 16 years, was first admitted to University College Hospital on August 16th, 1908, and remained until Sept. 8th, under the care of Sir Thomas Barlow. He came to the hospital complaining of œdema of the legs and swelling of the face in the morning, which had come
months and had steadily

for

close attention. It
the operation, as if
ought, and that after
rosis. The patient's
mother brought alarmist accounts of him after his departure from the hospital, which led us to believe he was *in extremis* and enabled us to readmit him for a long period into the hospital.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The Council has awarded the Harben gold medal for eminent services to the public health, which it is empowered to do triennially, to his Excellency Professor E. von Behring, M.D., Marburg, Germany, and has appointed Brevet-
M.B., R.A.M.C., Pro-
College, the Harben
Angelo Celli, M.D., Rome, the Harben lecturer for the year 1911. As already announced, the Harben lectures for 1909 will be delivered by Professor R. Pfeiffer, M.D., Breslau, in the lecture room of the institute on Monday, June 21st,
June, and Friday, June 25th, at 6 P.M.

PROPOSED INTERNATIONAL STANDARD FOR THE PHYSIOLOGICAL ASSAY OF THE HEART TONICS OF THE DIGITALIS SERIES.[1]

BY E. M. HOUGHTON, M.D. MICH. UNIV.

IT is a truism that therapeutic accuracy depends largely upon the uniform activity of the medicinal products at the disposal of the prescriber. Laboratory workers of the last quarter of a century have done much to point out the fallacies of empiricism and to devise ways and means for placing the practice of medicine on a more scientific basis. Much credit is due to the chemist for the development of methods of assay whereby the identity and purity of many of the most important medicinal substances may be determined, but it is becoming more and more clearly recognised that there are a number of much used drugs which are not amenable to chemical assay. The heart tonics of the digitalis group stand out conspicuously on account of their chemical properties, toxicity, and therapeutic importance as the chief representative of this class.

To Schmiedeberg, Fraser, Kiliani, and many other workers we are indebted for our knowledge of the chemistry of this group. It is not necessary to point out the many discrepancies that appear in the results of these workers, but owing to the variations in the properties of the crude drug as it appears on the market and the ease with which chemical decomposition takes place, it is impossible to reconcile these views and to accept them as final.

"We are not generally accustomed to think of the heart tonics as being the most poisonous remedies employed in therapeutics, yet it is true. According to some of the best authorities, the maximum dose of extract of digitalis is about one-half as great as the maximum dose of extract of belladonna, while strophanthin, the active principle of strophanthus, is three times as poisonous as atropine, ten times as poisonous as strychnine, and 12 times as poisonous as absolute hydrocyanic acid. It would be considered dangerous pharmaceutical practice to allow preparations containing atropine, strychnine, or hydrocyanic acid to be sold, without first being subjected to careful chemical assay and standardisation. The United States and other pharmacopœias give elaborate methods for the exact quantitative determination of these constituents; while, owing to the fact that the contained active principles of the heart tonics are glucosides, so easily decomposed by chemical manipulation that an assay cannot be made, no directions whatever are given for the determination of the physiologically active properties of the galenical preparations and the tests for the purity of the respective glucosides are of little value. Crude digitalis, strophanthus, &c., may be mixed to a greater or less extent with foreign material or inferior drugs when they come into the hands of the pharmacist or manufacturing chemist. By careful botanical examination the adulterating substance can be detected, and the advisability of garbling or rejecting the lot will depend upon the extent of impurities."[2]

During the autumn of 1896 I had occasion to test, by a method to be discussed later, four samples of strophanthin, "three of which were supposed to be chemically pure. There was found such wide variation in activity that one was 93 times as fatal as another; the strength of the remaining two varied between the above limits. No two samples were even approximately the same strength. What a chance for a sudden fatal termination of an apparently improving heart case!"[3]

Keller[4] concluded as the result of his researches that the therapeutic value of digitalis could be measured in terms of digitoxin, it being assumed that the other constituents were of so little value that they could be ignored. Without going into details, suffice it to say that in 1898 one of my assistants, a trained chemist, working upon known material, was unable to obtain results that would be considered of quantitative value, but was able to show, by determining the minimum fatal dose of the material for frogs, that reasonably constant results could be obtained by the physiological test (unpublished). These results were confirmed by Ziegenbein[5] by determining the minimum fatal dose for frogs and the digitoxin content. Likewise, Famulener and Lyons[6] arrived at the same conclusion from similar experiments. Barger and Shaw[7] showed that tinctures of digitalis were approximately from three to seven times as toxic as the digitoxin obtained from them. Focke and Fromme[8] were also unable to accept Keller's conclusions.

From these citations and others that could be referred to it is evident, since Keller's method has been looked upon as the most reliable chemical method proposed for digitalis (and the chemistry of the other heart tonics, with the exception of strophanthus, is still more involved), that chemical methods are insufficient for the valuation of the physiological activity of the heart tonics. Clinical experience and laboratory experiments have for generations shown that the variation in the activity of these drugs is very great. The age of the plant, method, and time of gathering and drying, preservation or storage, &c., all have more or less influence upon the active constituents contained.

In view of the many clinical observations showing the variation in the physiological activity of these preparations as they are dispensed for the treatment of patients; in view of the confirmation of these observations by numerous laboratory investigators using different methods of physiological assay for measuring such value; in view of the great importance that would accrue to science through the adoption of uniform methods; in view of the great toxicity of these compounds as compared with other and generally conceded deadly poisons which can be assayed by chemical methods; and, finally, in view of the impossibility of assaying these drugs by chemical methods, I believe that this section of the Congress should appoint a committee composed of not fewer than three members, who are actively engaged in pharmacological work, from each country desiring to participate, to consider before the next meeting of the Congress the different methods of physiological assay that have been proposed for measuring the value of the heart tonics, and to determine by exhaustive experiments upon animals the simplest and most reliable methods of assay, the precautions necessary to obtain uniform results, and the best method of expressing the results obtained in language intelligible to the practising physician.

There is no gainsaying that the Ehrlich method of assaying antidiphtheritic serum, which has been adopted by most civilised countries, has been of inestimable value in allowing physicians of all countries and languages to express and consider the results that have been obtained through the specific application of antidiphtheritic serum.

In America the subject of standardisation of antitetanic serum has recently been considered at length by a special committee appointed by the American Bacteriological Society for such purpose, and they were able to agree upon a method of assay for antitetanic serum that has been accepted by the United States Government, and which has brought about uniformity in strength of the serum prepared in that country. A different method is employed in Germany, and none at all, I believe, in Italy, France, England, and other countries. How much better it would have been for the subject to have been settled by an international committee, such as is proposed for the investigation of the proper methods of assay for the heart tonics. Such a committee, working together for the purpose of determining from a practical scientific basis the best and simplest method of assaying and expressing the value of these products to the therapeutist, would accomplish work of world-wide importance to science and to humanity. It is unnecessary to dwell longer on the matter, as the truth is *self-evident*.

For consideration I desire to present a method more or less modified that has for nearly 15 years been in almost daily use in the laboratory under my supervision. As a matter of history it may be *stated* that the first experiments were made in the autumn of 1894, the method itself being suggested by Professor Ehrlich's results obtained by testing antidiphtheritic serum.

The method was first published in a paper entitled "The Pharmacological Assay of the Heart Tonics," which was read before the Section on Materia Medica, Pharmacy and Therapeutics of the American Medical Association, June 7th-10th, 1898, and in which a detailed method of assay for the preparations of strophanthus was given as follows:—

---

[1] [illegible] read before the Pharmaceutical Chemistry Section of the [illegible] Congress of Applied Chemistry on May 31st, 1909.

[illegible]

is best, when one has [illegible] the frogs separated [illegible] over three grammes; [illegible] for strophanthin, th[illegible] strophanthus, those weighing 18 to 21 grammes for tincture digitalis, &c. Frogs weighing less than 30 grammes can be obtained at a very reasonable price from fishermen, as they are too small for the table. However, it is necessary that from the moment of capture they be handled with great care and kept in wet moss, &c., until they arrive at the laboratory, when they should be at once transferred to suitable ponds.

The method of administering the poisons and observing results may [illegible] ac. Great [illegible] ill allow a [illegible] the frogs [illegible] containing about a quarter of an inch of water. It will be necessary to inject several series of about five frogs each for each sample of the drug to be assayed, a first series to be injected with drug of known standard strength. After testing a large number of tinctures of strophanthus I found that 0·00015 c.c. per gramme body weight represented fairly well the toxic activities of an average sample of tincture prepared from strophanthus (Kombé). The minimum fatal doses of tinctures of strophanthus prepared from various lots of drug obtained from the American market were found to be as follows:—

1	0·00015	8	0·00015
2	0·00026	9	0·00022
3	0·00015	10	0·00017
4	0·00012	11	0·00016
5	0·00013	12	0·00015
6	0·00015	13	0·00025
7	0·00010	14	0·00033

The several tinctures were prepared by one process and with the same menstruum.

[illegible]

greater.

[illegible]

	Minimum fatal dose.
July 6th, 1897	0·00015
Oct. 19th, 1897	0·00015+
Dec. 23rd, 1897	0·00015
Feb 23rd, 1898	0·00015+
April 25th, 1898	0·00015

The loss in strength was so little in nearly one year that it came within the limits of error. Similar results are observed in regard to the permanence of a concentrated tincture of strophanthus.

Observations continued since the above was written 11 years ago have [illegible] whe[illegible] Thi[illegible] parations, as our experiments show quite conclusively that there is a loss in activity from month to month, even though [illegible] exceeding care.

[illegible] the potency of the standard preparation of strophanthus, great care was exercised in the selection of the frogs for the purpose in order to have those of as nearly uniform resistance as could be obtained. Likewise, a large number of frogs were used in making the several assays. I have not had occasion since 1898 materially to change the details of the method of making the assay or deriving standards for the other heart tonics.[9]

The application of the method may be briefly described as follows.

1. *Rules to be observed in order to obtain the most accurate results.*—The reaction chosen as a measure should be the most constant and characteristic obtainable for each given drug. The kind of animal chosen for making the observation [illegible] on is most clearly dis[illegible] making a test should be [illegible] as possible from one another in weight, temperament, &c., in order that the resistance of the several animals employed for making a test shall be as uniform as possible. The animals employed for the experiments should be kept under identically the same conditions just before and while the experiments are being made: the same food, the same degree of temperature, &c. In making a quantitative assay the strength of the unknown should be compared with the strength of a standard preparation of the same drug, the assay of both being made at the same time, and the conditions of the experiments being precisely the same in both cases. The standard adopted must possess the pharmacological activity of an average preparation. This standard is obtained by mixing equal parts of not less than ten lots of the preparation derived from the same number of lots of crude drug, which have been determined to be of first-class quality by physical and botanical examination. The action of the drug being assayed should, if possible, be compared with the action of the standard upon the same animal, and in those cases where this cannot be done a sufficient number of animals of as nearly uniform resistance as possible should be employed to rule out any individual idiosyncrasy.

2. *Apparatus.*—Small wire frog baskets with legs and covers or frog glasses and plates will do, care being taken not to set the baskets too deeply in water and not to fill the plates sufficiently full of water to drown the animals. The water should cover the bottom of the baskets or plates about one-fourth inch. Small balance for weighing the frogs. Volumetric flasks for diluting the preparations to be assayed, and glass pipettes, graduated into hundredths of a cubic centimetre, with long narrow points, or better, supplied with needle-points for injecting the frogs.

3. The strength of the preparation being assayed is to be compared with the strength of the standard, the two being tested at the same time and under the same conditions. (See directions already given for the assay of tincture of strophanthus.) The standard is obtained according to the method outlined in the general remarks, which is an average sample of the preparation made from first-class crude drug. 1 cubic centimetre or gramme of the preparation to be assayed is diluted with normal saline solution to make the dilution such that the amount to be injected into each frog shall be about 0·5 cubic centimetre, the same care being exercised in making the solution as would be in making up volumetric solutions for chemical assay. The frogs, which are of the same species and have been kept under the same conditions, are weighed and the weights recorded, the frogs being marked so that they can be readily identified. The frogs should not differ more than 3 grammes in weight, but may be of any size, the aim being to have the resistance uniform. It will be necessary to inject several series of frogs approximately as follows:—

FIRST SERIES.—A *Frogs Injected with Standard.*

Number of frogs.	Weight of frogs.	Amount of tincture injected per gramme body weight.	Result at end of 12 hours.
1	15 grammes.	0·0001	Alive.
2	16 "	0·00015	"
3	15 "	0·0002	Dead.
4	17 "	0·00025	"

The killing dose is between 0·00015 and 0·0002.

---

[9] An article by the writer on Physiological Testing was published in the last two editions of the National Standard Dispensatory.

B. *Frogs Injected with Tincture to be Assayed.*

Number of frogs.	Weight of frogs.	Amount of tincture injected per gramme body-weight.	Result at end of 12 hours.
1	16 grammes.	0·0001	Alive.
2	15 ,,	0·00015	,,
3	17 ,,	0·0002	,,
4	15 ,,	0·00025	Dead.

The killing dose is between 0·0002 and 0·00025.

SECOND SERIES.

A. *Standard.*

Number of frogs.	Weight of frogs.	Amount of tincture injected per gramme body-weight.	Result at end of 12 hours.
1	15 grammes.	0·00015	Alive.
2	16 ,,	0·00016	Dead.
3	15 ,,	0·00017	,,
4	17 ,,	0·00018	,,
5	16 ,,	0·00019	,,

The killing dose is between 0·00015 and 0·00016.

B. *Tincture being Assayed.*

Number of frogs.	Weight of frogs.	Amount of tincture injected per gramme body-weight.	Result at end of 12 hours.
1	16 grammes.	0·0002	Alive.
2	15 ,,	0·00021	,,
3	15 ,,	0·00022	Dead.
4	16 ,,	0·00023	,,
5	17 ,,	0·00024	,,

The killing dose is between 0·00021 and 0·00022.

THIRD SERIES.

A. *Standard.*

Number of frogs.	Weight of frogs.	Amount of tincture injected per gramme body-weight.	Result at end of 12 hours.
1	15 grammes.	0·00016	Alive.
2	16 ,,	0·00016	Dead.
3	16 ,,	0·00016	,,
4	17 ,,	0·00016	,,
5	16 ,,	0·00016	Alive.

Minimum fatal dose 0·00016.

B. *Tincture being Assayed.*

Number of frogs.	Weight of frogs.	Amount of tincture injected per gramme body-weight.	Result at end of 12 hours.
1	16 grammes.	0·00022	Dead.
2	17 ,,	0·00022	,,
3	15 ,,	0·00022	Alive.
4	17 ,,	0·00022	Dead.
5	16 ,,	0·00022	Alive.

Minimum fatal dose 0·00022.

It will be observed in the above illustration that the minimum fatal dose for the standard tincture of strophanthus was a little larger than that which had been previously adopted, but, in arriving at the percentage value of the tincture, proper correction is made for this variation from the standard by the figures used.

According to the results obtained from the injection of the three series of frogs, 0·00016 cubic centimetre of the standard tincture has the same killing power as 0·00022 cubic centimetre of the tincture being assayed. Hence, the tincture possesses a strength of $\frac{0\cdot00016}{0\cdot00022} = \frac{16}{22} = 72$ + per cent. of standard.

Experience has shown that the figures given in the following list indicate what may be taken as a tentative standard for the several preparations mentioned.

	Minimum fatal dose per gramme body weight.
Digitalis, fluid extract, U.S.P., 1890	0·0015
,, solid extract	0·0005
,, powdered extract	0·0005
,, tincture, U.S.P., 1900	0·015
,, digitalin (German)	0·00005
Squill, fluid extract, U.S.P., 1890	0·0012
Strophanthus, tincture, U.S.P., 1900	0·000075
Convallaria, fluid extract of rhizome and roots, U.S.P., 1900	0·00025
,, ,, ,, herb	0·00015
,, ,, ,, flowers	0·00009

These figures were derived in a manner similar to that used for the derivation of the minimum fatal dose for the standard tincture of strophanthus, as previously stated. Reference to the following synopses dealing with strophanthus, digitalis, squill, and convallaria shows how accurately these figures correspond with the results obtained in routine practice in a large manufacturing laboratory. The averages indicate the actual results obtained on all the samples of the preparations tested since the year 1901. The records for the previous five years were unfortunately destroyed in a fire that we had in our laboratory in 1903, consequently the figures for that period are not available. It should be observed that the figure for the standard tincture of strophanthus was given in the paper published in 1898, and that it closely approximates with those derived from the assay of 134 samples of tincture of strophanthus tested, as stated, since the year 1901.

SYNOPSES OF RESULTS.

Tincture of Strophanthus, U.S.P., 1890 (5 per cent.).

—	M.F.D.	Units.
Standard adopted in 1897	0·00015	6666
Revised standard subsequently adopted... ...	0·00016	6250
Average for 134 samples tested since 1901 ...	0·000167	5985

Fluid Extract of Digitalis.

—	M.F.D.	Units.
Standard adopted in 1898	0·0015	666
Average for 83 samples tested since 1901 ...	0·00142	701

Fluid Extract of Squill.

—	M.F.D.	Units.
Standard adopted in 1901	0·0012	833
Average for 61 samples tested since 1901 ...	0·00123	807

Fluid Extract of Convallaria (Rhizome and Roots).

—	M.F.D.	Units.
Standard adopted in 1900	0·00025	4000
Average for 30 samples tested since 1901 ...	0·000245	4067

A further development of this method of assay has convinced me that it would be important to adopt "a heart tonic unit" as a means of expressing the physiological values, the number of such units to be derived directly from the minimum fatal dose of the given preparation. A convenient unit is obtained by dividing one by the minimum fatal dose per gramme body-weight of frog; or, in other words, the number of units will be the reciprocal of the minimum fatal dose. To illustrate: if the minimum fatal dose of a given drug per gramme body-weight of frog is found to be equivalent to 0·01, then the given substance, *assuming that* it belongs to the group of heart tonics, would contain 100 heart tonic units: (m.f.d. $\frac{1}{0\cdot 01}$ = 100 h.t.u.) This rule can be applied to any of the heart tonics as a means of expressing such values in whole numbers.

Instead of stating the full number of heart tonic units in all cases round numbers can be used, which do not vary more than a given per cent. from the actual number of units. Reference to *tables shows* what *may* be *accomplished*.

A correction will be necessary where the minimum fatal dose of the standard is more or less than that mentioned in [illegible] such correction to [illegible] According to the [illegible] ndard divided by the minimum fatal dose of unknown

$$\left(\frac{\text{m.f.d. of standard}}{\text{m.f.d. of unknown}} = \text{per cent. of standard}\right)$$

equals the percentage value of unknown. The percentage value of the unknown can easily be converted back into the normal minimum fatal dose as shown below.

M.F.D.	Exact H.T.U.	Approximate H.T.U.	% error.
0·0001	10000	10000	0
0·0002	5000	5000	0
0·0003	3333	3330	0·9
0·0004	2500	2500	0
0·0005	2000	2000	0
0·0006	1666	1660	0·4
0·0007	1428	1430	0·1
0·0008	1250	1250	0
0·0009	1111	1110	0·1
0·0010	1000	1000	0
0·0011	909	910	0·1
0·0012	833	830	0·3
0·0013	769	770	0·1
0·0014	714	710	0·5
0·0015	666	660	0·9
0·0016	625	620	0·8
0·0017	588	590	0·3
0·0018	555	550	0·2
0·0019	526	520	1·1
0·0020	500	500	0
0·0100	100	100	0

M.F.D. = minimum fatal dose per gramme body-weight of frog.
H.T.U. = heart tonic units.

In actual practice a table can be constructed similar *to the above for all the values that will be derived in* the testing of the heart tonics under all conditions. These may be printed on a sheet or sheets of paper and kept for reference in a book form or placed on a chart to hang on the wall of the operation room and used in the same manner as interest or logarithm tables. Such practice would obviate entirely the necessity for the person doing the testing to make mathematical computations unless a correction would be needed, in order to convert an abnormal minimum fatal dose into a *normal minimum fatal dose*. These variations also can be worked out and converted into tables.

Conclusions.—1. It has been shown by numerous laboratory workers that it is impossible to determine the value of the heart tonics of the digitalis series by chemical assays. 2. *It is a well-recognised fact that the toxicity of these* products warrants that every effort should be made to present preparations of them of as uniform value as possible. 3. Experiments upon animals have demonstrated conclusively that the variation in the physiological action of some of these products is extremely great. 4. It is urged that this section appoint an international committee to determine and recommend the best method of physiological assay of the heart tonics of the digitalis series and an international standard, "heart tonic unit," to express the physiological value of the pharmaceutical products of this series. 5. The author puts forth the above method of physiological assay, which is the result of nearly 15 years of *laboratory study, for consideration* as a possible solution of this problem.

Detroit, Michigan, U.S.A.

RUPTURE OF THE SPLEEN; REMOVAL; RECOVERY.

BY T. S. LUKIS, M.B.

THE patient, a schoolboy, aged seven years, was admitted into St. Bartholomew's Hospital under the care of Mr. D'Arcy Power on May 12th, 1908, at 10.30 P.M., having been run over by a van weighing two tons. It was alleged that the wheels passed right across the boy's abdomen.

On admission the patient was collapsed; his face was pale, his lips were blue, and his body was cold and clammy. He had *passed fæces* and urine under him, but *no blood*. He was very restless, turning about, and preferring to lie on his face. His pulse was 140 and irregular, the temperature was 96° F., and the respirations were shallow, numbering 34. An examination revealed some bruising of the left side of the chest and abdomen. There was a graze on the left side of the chest over the ninth, tenth, and eleventh ribs and another graze on the abdomen just above the anterior superior iliac spine. The appearance suggested that the wheels did not pass right over the abdomen, but merely grazed the left side of it. The abdomen was tender, rigid, and resonant all over and moved very little with respiration. The child complained of pain, especially in the left lumbar region. No free fluid and nothing abnormal *could be felt in the abdomen. Mr. G. E. Gask saw the case* and decided not to operate, the condition of the child being unfavourable.

The patient was very restless all night. His pulse kept at 140 and was irregular. His temperature rose to 97°. He [illegible] free from blood and he vomited [illegible] e pulse became much worse and [illegible] abdomen was much distended but the distension was partially relieved by an enema at 8 A.M. *For the rest of the day until* 5 P.M. the pulse could not be felt, but it then returned to 130 and the patient seemed much better, his colour improving.

On the following day Mr. D'Arcy Power decided to operate, the general condition of the child having improved greatly. At *3.30* P.M. chloroform was administered and a vertical incision was made 3½ inches long through the left rectus muscle above the umbilicus, 1½ inches from the middle line. The peritoneal cavity was opened and was found to contain a quantity of blood-clot and blood which was washed out with saline solution at a temperature of 110°. The anterior surface of the left lobe of the liver was found to be grazed over an area of about the size of a crown-piece, but had stopped bleeding. The spleen was *drawn out of the wound and was found to* be badly lacerated, the lower third [illegible] rest, and there [illegible] hilum. The or[illegible] mesentery which ruptured when an attempt was made to ligature it. *As bleeding had also stopped in the spleen*, some of the arteries of which were very definitely thrombosed, [illegible] ligature the pedicle. The [illegible] ning had never been very [illegible] inage tube was left in the wound to be an index of possible further hæmorrhage. The child came through the operation very well, and there was no further extensive hæmorrhage, the drainage tube being removed on the sixth day, when the pulse had quieted down to 100. *The patient* made an uneventful recovery.

The points of interest in the case are. First, that a delay in operating, amounting to 42 hours, did not prejudice the patient's chance of recovery, but probably saved his life. Mr. G. S. Simpson, in an article in THE LANCET of August 11th, 1906, *mentioned* that of 28 cases of ruptured spleen which he had collected three operated on within two

APHASIA SUCCEEDED BY JACKSONIAN EPILEPSY; OPERATION; RECOVERY.

BY W. ALEXANDER, M.D. R.U.I., F.R.C.S. ENG.,
VISITING SURGEON TO THE LIVERPOOL WORKHOUSE HOSPITAL.

A MAN, aged 33 years, was admitted to the Liverpool Workhouse Asylum Ward on Nov. 4th, 1908, with a certificate of insanity. He was brought to the hospital by a police constable, who had found him lying in a doorway in a nude condition. On examining him in the asylum next morning it was found that it was aphasia and not insanity that he was suffering from, and he was transferred to the medical wards. He understood what was said to him, and could assent to, or dissent from, any statement by nodding or shaking his head. The pupils were equal, there was no facial paralysis, but partial loss of power of the right hand and arm (the hand lay in a semi-flexed position). There was also some athetosis. On the 8th the condition was unaltered except that the fingers of the right hand had become more flexed and the athetosis had ceased. A firm depressed scar was visible on the scalp over the left anterior parietal region, the scalp moved freely, and the bone was not apparently injured. He remained in this condition till the 9th. The man with whom he lodged called on Nov. 8th and said the patient was often the worse for drink, that on the night in question (Nov. 1st) he was quarrelsome, had called his wife names, and had been turned out of doors in consequence. He did not think the patient could not speak; he was noisy. He could not say how the patient passed his time from Nov. 1st to Nov. 4th, the day of admission to asylum. At 5.30 A.M. of the 9th the patient had a right-sided epileptiform attack affecting the arm, afterwards the leg and face, with only slight loss of consciousness. When the twitching of the right hand began the patient was quite conscious, but as the attack proceeded he gradually became unconscious. He had another fit in the evening of the same day at 11.30. On the 10th the patient had three similar fits during the day. On the 11th he had 20 fits and was very exhausted, the pulse-rate increasing and the pulse becoming feebler. An epileptic mixture containing bromide of potassium was prescribed. On the 12th he had six fits in an hour. He was transferred to the surgical ward at 2.30, as the fits still continued and the patient became feebler. The skull was trephined over the left motor area. A rectangular piece of bone, three inches by two inches, was removed. The dura mater was normal and was opened by four slits, each extending right across the breadth of the opening in the bones. This permitted the cerebral convolutions to be easily examined over the greater part of the motor area. At the posterior extremity of the third left frontal convolution a conical elevation could be distinctly seen. The cone was formed of apparently healthy brain substance. The needle of an exploring syringe was passed into the apex and a full measure (one drachm) of clear fluid was withdrawn. A pair of closed sinus forceps were then passed along the needle of the syringe into the cavity, and on separating the blades rather more than half an ounce of fluid came away. The veins of the pia mater were congested, and along each side of the veins broad areas of whitish flocculent œdema were seen. Pricking the œdematous area gave vent to drops and spurts of clear fluid. The flaps and fenestrated dura mater were now bathed with normal warm saline solution and the flaps replaced and stitched up with silkworm gut. A small glass drainage tube was placed for 48 hours in the posterior angle of the wound. The head was well enveloped in sterile gauze and cotton wool. Not a single vessel had to be tied from start to finish of the operation, and no ligature of any kind was left beneath the replaced flaps. The bone removed was not replaced.

After operation the patient was rather restless, but at 10.30 P.M. he went to sleep and slept until 4 A.M., when, according to the nurse, he had a fit lasting two minutes. He then slept again and awoke at 7.30 A.M. On Nov. 13th he had a comfortable day, sleeping a good part of his time. After awaking from sleep in the afternoon he had two fits, one at 3.30 and one at 3.40. He could now move the flexed fingers of his right hand just a little. On the 14th he had a good night, with no fits. He could now say "yes" and "no" and a few other single words, but could not carry on a conversation. The head was dressed and the drainage-tube was removed, some clear fluid coming from it. He slept and dozed the greater part of the day. On the 15th he had slept well all night with no fits. He asked for what he wanted by signs and said a few words; he could also open the right hand and grasp with it. On the 20th he continued to improve; there were no fits; he could now carry on a conversation, though with difficulty. He told us that his name was ——, aged 33 years, a dock-labourer, that he was born in Liverpool, that his parents were dead, but that a brother and two sisters were alive. He could count up to 20, but always missed 18. By the 24th the patient could talk much better; there were no fits. He stated that the scar on his scalp was caused by a piece of coal falling on his head 16 years ago, when he was a miner at Wigan. He never had any fits before his admission to the hospital. He admitted having taken occasionally one or two glasses of whisky, but was not in the habit of getting drunk. He remembered the lodging-housekeeper putting him out on the street on Nov. 1st, but did not remember anything afterwards until he found himself in the male asylum, where male nurses attended him. He also remembered coming to hospital, where there were female nurses. The three days—Nov. 1st to Nov. 4th—are a blank to him. On Nov. 26th the stitches were removed. The wound healed by first intention and without pyrexia. On Dec. 4th the patient was allowed to get out of bed. There were no fits; the paralysis and aphasia were quite gone. He could count up to 20 without omitting any numbers. On the 16th he went out at his own request. On Feb. 5th he came to report himself. He had been working at the docks and could do a good day's work. There were no signs of any defect about him and he said he obtained jobs just as well as any other man, so that evidently no defect was noticed in the man by the agents of the employers who engage the men.

There are several points of interest in this case. The preliminary diagnosis of insanity was probably made in difficult circumstances, and was no doubt due to the history of violent conduct produced by drink and to his mute condition. The mutism of insanity and the inability to speak of aphasia are very different things and not likely to be mistaken for each other provided we are enabled to have a look at the eyes of the patient. A partially drunk aphasiac would make an error quite possible, but when he was sober there could be no doubt about the matter. It is also clear from the history, which was, however, very imperfect, that the aphasia came on between Nov. 1st and Nov. 4th, the night of his admission. He was quarrelling with his wife that night, and in consequence was turned out of the house in his night attire. From Nov. 1st to Nov. 4th is a blank to him and to us. The cyst, if cyst it was, or rather collection of fluid, must have formed or increased very rapidly during the three days to produce the aphasia and the paralysis. An aphasiac cannot very well quarrel, and he was probably not aphasic on Nov. 1st, and possibly the excitement and the drink or the "chucking-out" had something to do with the onset of aphasia soon after the quarrel. The cavity, when the fluid was removed, had no very distinct walls. We opened it up freely, but for obvious reasons we could not examine it so thoroughly as to be sure of its exact nature, since the patient was in a critical state and time was of the greatest importance. It was not in the ventricle, as it was near the surface and the cavity was limited in its extent. It seemed to be one of those adventitious collections of fluid that occur mysteriously in the tissues, and which form cysts in time by the pressure of their contents upon the periphery of the fluid effusion. In this case the effusion was too recent to permit the formation of any distinct cyst wall. We may ascribe the aphasia and the paralysis to the cyst. It was interesting to notice that the whitish flocculent œdema that is seen so frequently in operations on true epilepsy was present in the case. I am so familiar with œdema in our operations on epilepsy that I did not altogether expect to find it in this Jacksonian variety. That epilepsy is probably due to circulatory disturbance is now fairly extensively believed, and in this case the formation of the quasi cyst was in itself a circulatory disturbance. The *modus operandi* was also influenced by circulatory considerations, to which this successful case gives a considerable amount of support, but the questions are too large to discuss further on this opportunity.

Liverpool.

A CASE OF CATALEPSY OCCURRING IN A BOY AGED 15 YEARS.

BY DONALD E. CORE, M.B., CH.B. VICT.,
RESIDENT MEDICAL OFFICER, BARNES CONVALESCENT HOSPITAL, CHEADLE.

THE patient was brought into the out-patient department of the Derbyshire Royal Infirmary with a history of having had three "fits" during the preceding six weeks. Up to that time he had been perfectly healthy, and there was no evidence of his having had fits or convulsions during infancy. His previous medical history was good, but he appears to have been very backward while at school. His father at the time of his admission stated that in these fits the boy had first become very stiff for a short time and then jerked himself about, but had never fallen, as there had always been time to recognise what was about to happen and to get the boy into a chair. There had not been any passing of urine in these attacks, neither had he ever bitten his tongue. There was no history of fits of any kind in any other member of the family. The last fit occurred some two weeks before the patient was first seen, and was apparently followed by a state of stupor, in which the boy would not feed himself, and had to be made to pass his urine. Once his attention was drawn to his necessities, however, he passed it himself naturally. Otherwise he had been in a condition of blankness, and it was for this condition that he was brought into the hospital.

When first seen the boy was in an absolutely passive condition. He allowed his limbs to be put into any position, and made no attempt either to resist or to alter their attitude. The extremities could be moulded into positions as if they had been made of wax. He was, however, alive to painful stimuli, and resented pinpricks by frowning and finally by turning his body away from the stimulus. The only muscles which were active were those of the eyes; these were moved voluntarily, and the patient watched proceedings with interest. The general condition was very good, the boy being well grown and with remarkably well-developed muscles.

Nervous system.—Motor: Active movements, with the exception of the ocular muscles, were in entire abeyance. The legs and arms could be put into any position without the least resistance, and they were maintained in these attitudes until, the weight of the limbs overcoming the muscular strength, they slowly dropped. Thus, the arms being erected over the head, they remained in this position for over a quarter of an hour. Then they began to sway, and the excursions becoming wider and wider they finally lay by the side. The legs fell more quickly, being exhausted in from five to ten minutes. After the sensory system had been investigated by the use of a pinpoint the passivity of the limbs lessened, and very considerable strength was manifested. There were no tremors and no evidence of any head retraction. The boy on admission was able to stand, but would make no attempt to walk. He had to be led about as though he were blind. The muscular tone was normal. Sensory: There was much resentment displayed to painful stimuli. In most cases this was manifested by a screwing up of the facial muscles. Reflexes: The knee-jerks were present and normal. Ankle clonus was absent on both sides; Babinski's reflex was similarly absent on both sides. The superficial reflexes were present and active. Bladder and rectum: There were incontinence of urine and marked constipation. Special senses: There was no nystagmus. The right pupil was slightly larger than the left. The discs were normal. The pupils reacted normally. On his admission it was impossible to say whether he was able to hear or not. He took no notice of anything that was said to him. Mental: Entire negativism, altering occasionally to a state of anger. There was no evidence of any cerebral irritation. Speech: Absent. There were no trophic lesions of any kind present on his body. The heart, lungs, and abdominal organs were normal.

The boy would not feed himself and had to be spoonfed. Shortly after his admission he would not swallow what was put into his mouth, and he had to be nasal-fed. After the first meal given in this way, he took his food perfectly well if it was placed in his mouth. On the eighth day of his stay in the hospital he developed a very slight but quite definite squint, the left internal rectus apparently being at fault. This, after varying from day to day, disappeared within a week of its appearance.

The boy was treated with galvanism and massage, and although at the time of application he seemed to improve, he remained in the state described for over 16 weeks. During this period he never, apart from electrical stimulation, made a single voluntary movement. He lay on his back staring at the ceiling and generally soaked in urine. While being galvanised he turned himself about in order to evade the battery, and on several occasions shouted out, but as soon as the current was taken off he relapsed into his former state. Some ten weeks after his admission contractures of the fingers made their appearance, and any effort to extend them met with the most violent resistance. This was followed by flexion of the legs on the thighs, and of the thighs on the trunk, but the mental condition remained just as it was, and the limbs when straightened could be moulded in the same way as when he was first seen.

Sixteen weeks after his admission the boy was suddenly heard singing in the night, and shortly after he spoke a few words apart from electrical stimulation. From this time he recovered rapidly, but for some time after he was able to feed himself and to speak his muscles were in their original state of waxy flexibility. Thus after having been given a plate of rice and a spoon he would sit and stare at the food without making the least attempt to eat it. Then when some was lifted into his mouth he would start feeding himself and would continue to raise the spoon to his mouth long after the plate was empty. When told to stop he would slowly obey. If he was questioned, he would at first make no effort to answer, neither would he look at the questioner, but after a long pause he would in a peculiarly monotonous tone reply. This transition state rapidly passed off, and the boy became what was probably his normal condition. This was one of irritating stupidity, mingled with a low degree of cunning. He was intensely disobedient and stole consistently from the other patients in the ward. He had no idea of decency, and would get out of bed the moment the nurse's back was turned, and, taking off his clothes, would run about the ward naked. He was able to read and write and to work out simple arithmetical problems. He was sent to the Derby Infirmary Convalescent Home, where he stayed three weeks.

The temperature throughout the whole period of his stay in the hospital was normal. There was never any albuminuria.

My reasons in publishing this case are its rarity and the duration of the condition. When he was first seen the question raised was whether he had not some meningeal trouble, and this was made all the more probable by the inequality of the pupils and the squint. There was never any elevation of the temperature, and the pulse was always perfectly normal. There were no signs of any cerebral trouble, and a diagnosis of hysteria was made. This was confirmed by the appearances of the contractures. A diagnosis discussed was one of post-epileptic stupor, but the length of time which had elapsed between the last fit and his admission, 14 days, put this out of the question. Then again, the fits were not perfectly typical of epilepsy.

Of the many hysterical manifestations the case conformed most closely to that known as catalepsy. This state nowadays is considered to be almost always hysterical, although Whitla in his recent text-book says that it may be associated with such diseases as meningitis and melancholia. Osler, Fagge and Pye-Smith, and Savill all agree in regarding it as purely hysterical. Kraepelin, on the other hand, looks upon catalepsy as a symptom more or less synonymous with "flexibilitas cerea," and considers it characteristic of dementia præcox. Maurice Craig, under the heading of "Catatonic Stupor," describes the following condition associated with mental depression, delusions, and hallucinations: a markedly resistant condition of the muscles, which, [illegible] geration.

Dr. Hack Tuke, in Allbutt's "System of Medicine," states that catalepsy may be a condition *per se*, or it may be associated with mental symptoms. He describes a case which resembles the one above as belonging to the former class. In his opinion it is a rare condition and one which almost always affects young females. The onset is generally ascribed to mental shock of some sort and the symptoms come on suddenly. In the case I have just described there were no mental symptoms of the nature of delusions or hallucinations. The boy was certainly mischievous and remarkably unintelligent, but he did not differ in these respects from many boys of whose mental health there is no doubt. Dr. Hack Tuke further remarks that the memory for events which have occurred during the attack may or may not be impaired. In my case many small details of ward discipline and also fragments of conversation which had been spoken at his bedside during the stage of negativism were remembered with the greatest clearness.

The pathology of these cases is uncertain. The immediate factor at fault is the motor inhibitive function of the cerebrum, but this does not carry us very far to their solution. The primary trouble is essentially that of the group of functional disease to which it belongs—namely, the hysterical diseases. In the consideration of mental disturbances from the standpoint of function, one can recognise three factors which, acting normally, are responsible for comprehension, thought, and memory. These three factors are the afferent, the central, and the efferent paths of the central nervous system. Any element of these three systems may influence one or all the elements of the other two. In highly developed organisms the afferent and efferent systems work upon each other through the central; for some actions, however, the activity of the central processes is not necessary. In health the central system works upon the efferent by a process of excitation and depression, the healthy exercise of these functions constituting judgment. In a steady state of health the central system does not materially alter or affect the normal impressions received from the afferent paths, but in disease it does, the result being delusions. Delusions are the result of a disturbed central mechanism—that is to say, they are the outward and visible sign of intrinsic central trouble. Intrinsic afferent trouble constitutes such diseases as blindness, deafness, and the like; intrinsic efferent trouble the various paralyses. A diseased action of the central mechanism on the efferent system results in disturbances of judgment. Most diseases of the mental organisation are referable to excessive, diminished, or perverted function.

In the case above considered, we may imagine the higher elements of the central mechanism to be, as it were, blotted out. That is to say, comprehension and thought, at the time of his attack, were non-existent. With the abolition of comprehension, the influence of this function on the actions disappeared, the lad manifesting no sign of judgment, and so arose such symptoms as refusal of food, incontinence of urine, and the plasticity of the limbs. Memory, as we have seen, was not altogether in abeyance, but was not associated with any efferent impulse. The trouble was one in which the highest functions only were concerned.

The recovery of many of these cases is not infrequently accompanied by an attack of maniacal excitement, as though the central mechanism, after its long period of inactivity, begins work with its functions exalted.

I am indebted to Dr. F. B. Thornton of Derby for permission to publish this case.

Cheadle, near Manchester.

REMOVAL OF SUPERFLUOUS HAIRS BY IMPROVED METHODS.

By A. HOWARD PIRIE, B.Sc., M.D. Edin.,
CHIEF ASSISTANT IN THE ELECTRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL

THE removal of superfluous hairs by means of electrolysis is a very satisfactory minor operation when well carried out. Frequently, however, a small scar is produced at the seat of operation, and in order to avoid such a scar a simple precaution is necessary which is not mentioned in works on medical electricity. Like all other operations, it must be performed intelligently and not blindly, without regard to the principles of electricity, anatomy, and physiology. It is often spoken of as if the root of the hair was burned by the electricity as a nævus is burned by a cautery point. This is quite a wrong view to take of the operation. The destruction of the root of the hair is caused by an acid or an alkali, generated at the positive and negative poles respectively. 1. If a needle which is not acted on by acids is used, such as gold or platinum, and it is connected to the negative pole, then nascent chlorine appears round the needle with the formation of hydrochloric acid and destruction of the hair bulb. It is as if a minute quantity of free hydrochloric acid had been injected into the hair follicle. 2. If a needle which is acted on by hydrochloric acid is used, such as zinc, the acid attacks the zinc, forming chloride of zinc, and this goes into solution; thus both hydrochloric acid and zinc chloride are set free in the hair follicle. In this case a little of the zinc remains in the follicle, but is not driven in to the surrounding cells, and therefore there is no staining of the skin where a corrodible needle is used, provided it is connected to the negative pole. 3. If a non-corrodible needle such as gold is used for the operation, and it is connected to the positive pole, free sodium is liberated at the surfaces of the needle; this at once combines with the water of the tissues to form caustic soda, which in turn attacks and destroys the root of the hair. 4. If a corrodible needle, such as a steel needle, be used and be connected to the positive pole free sodium is liberated at the surface of the needle, which at once becomes caustic soda, which attacks the iron, forming oxide, and hydrate of iron. This remains in the hair follicle and therefore does not stain permanently the skin. But there is a much more important action going on in this case which does stain the tissues, and that is the transport of iron ions from the steel needle into the actual cells of the skin, where they are fixed and remain as iron oxide or rust. For this reason a corrodible needle must never be attached to the positive pole in this operation. No pigmentation is therefore produced if one uses a corrodible needle, provided it is connected to the negative pole.

When the current is turned on and the needle which is attached to the negative pole touches the skin, acid formation at once begins. As the needle sinks into the hair follicle the acid also penetrates deeper till it reaches and destroys the bulb of the hair. The needle must be left a sufficient length of time to allow sufficient acid to collect in the follicle to destroy the root of the hair. But while the root is being destroyed, so is the skin around that part of the hair which is embedded in the upper layer of the skin. It is quite unnecessary to destroy more than the root of the hair, and this destruction of surrounding tissue is the cause of future scarring. This can easily be avoided by a simple method of insulating the needle to within a sixteenth of an inch of its point. When a needle is so insulated and thrust into the root of the hair, the free acid attacks only the root and therefore there is no scarring left after the operation. Patients have remarked to me on the decrease in the amount of reaction following the operation when the insulated needle has been used, and it is very striking to an operator who uses an insulated needle after being accustomed to a naked needle.

The method of insulating the needle is very simple. In the first place, I prefer to use a fine wire in place of a needle. I find the wire supplied with the finest hypodermic needle useful for the purpose. It is finer than a No. 12 sewing needle, which is the finest sewing needle obtainable. Another advantage of this wire is that it has not a sharp point and therefore is not so likely to leave the hair follicle and make a false passage. If too much force is used in introducing the wire it bends and makes further progress impossible. By its extreme fineness it finds its way down by the side of the hair, and in the case of hairs whose roots take a curved course in the skin it follows the curve instead of making a false passage, as the finest sewing needle does. Unless the point of the needle reaches the actual bulb of the hair the operation is useless. Therefore a fine wire with a blunt point is better than a fine sharp needle for the purpose.

The wire should be insulated as follows. Hold a piece of shellac in the left hand and the wire in the right. Heat the wire to redness in a Bunsen flame, and while red hot embed it quickly in the shellac all except its point and lift it out again quickly, thus leaving a sixteenth of an inch uncovered by shellac. There is thus a thin layer of shellac left on the wire, and it fits it so well that no irregularity appears to the naked eye in the outline of the wire as compared with its former state. The tip of the wire must not touch the shellac. One-sixteenth of an inch remains naked at the tip of the wire. The wire cuts into the shellac when it is red hot as one cats a banana with a knife.

Conclusion.—To sum up, the essentials of good results in this operation are: (1) connect the needle to the negative pole; (2) use a fine stiff wire as a needle (the wire supplied with the finest hypodermic needle is a suitable one); and (3) insulate the wire so that only the last one-sixteenth of an inch supplies the current. The advantages of this method are two—(1) no scarring after the operation; and (2) a lower per cent. of re-growth of hairs.

A SIMPLE METHOD OF DIAGNOSIS IN PARALYSES OF THE EXTRINSIC MUSCLES OF THE EYE.

BY ANGUS MACNAB, M.B., CH.B. EDIN., F.R.C.S. ENG.,
CHIEF CLINICAL ASSISTANT, ROYAL LONDON OPHTHALMIC HOSPITAL, ETC.

IT is quite unnecessary to insist on the importance of being able to diagnose the affected muscle in a case of diplopia; it is equally unnecessary to point out that the methods generally adopted entail either a very efficient *memory or a severe mental effort on the part of the physician* making the diagnosis. The almost invariable difficulty which students find in their attempts to decide which muscle is affected seems to show that the methods employed do not allow of the diagnosis being readily and exactly made.

It appears impossible to bring any new observations to bear on such an old subject, but the grouping of the facts here given and the generalisations from them appear to make the subject easy of comprehension and the diagnosis of the particular muscle simple, the only requirement being the elementary one, that the direction, point of insertion, and action of each of the muscles should be known.

The diagnosis proceeds in stages. I., Is there a muscle paralysed? II., What is its action? III., Which eye is affected? IV., W[illegible] *action is affected?* [illegible] the particular the[illegible] till the final test [illegible] two similarly acting muscles.

It will be noted that the scheme here elaborated pays no *attention to crossed or homonymous diplopia, though the* first step taken by many is to determine, Is the diplopia homonymous or crossed? This method of proceeding may be [illegible] oblique paralysis [illegible] the eyes, and [illegible] homonymous; but if the patient previously had an exophoria, the divergence due to it might exceed the convergence due to the paralysis and the diplopia would be crossed, which, of course, would contra-indicate a superior oblique paralysis. The general statement given below as Section 4, that the angular separation of the images is greatest when the object is in the line of the affected tendon and the torsional displacement, if any, is greatest when the line from the object to the eye cuts the affected tendon at right angles, will be found very useful.

There are several fallacies which should be avoided if a correct diagnosis is to be arrived at. The eye which obviously deviates from the object fixed is not necessarily the one affected, for the patient may have very good vision in the affected eye, and bad vision in the one whose muscles are normal; the secondary deviation of the unaffected eye may then be mistaken for the primary deviation of the affected one. In testing for torsional displacement, too, the vertical image is not necessarily due to the unaffected eye. The patient will often say that the coloured object (candle) is leaning and the white one is vertical; and then if the coloured glass be moved to the other eye the white object is still ver[illegible] unnecessary to det[illegible] the important poi[illegible] of inclination of[illegible]

T[illegible]

1. *A muscle is paralysed when a diplopia occurs in one of the field of vision or when there is diplopia over the whole field and the separation of the images increases in one direction.*

[illegible] the patient is directed [illegible]ssively raised, lowered, [illegible] two candles in some [illegible] positions the distance [illegible]ions, there is a muscle paresis.

2. *The direction in which the diplopia is greatest*[1] *indicates the direction of action of the affected muscle.*

[illegible] downwards.

3. *The image projected further in the direction of greatest diplopia is formed by the affected eye.* When the candle is moved in the direction in which the diplopia increases the image which moves most rapidly in that direction is the one formed by the affected eye.

[illegible]

4. *The separation of the images is greatest when the eye is looking along the line of the tendon of the affected muscle* or when the object is opposite the end of the affected tendon.

[illegible] *will be greater when* [illegible]

This method has been found very efficient and has stood the test of three years' application to all the cases of muscle paralysis occurring in two busy hospital clinics. It requires no diagram to be memorised, and calls for the minimum of intelligent coöperation on the part of the patient.

---

[1] [illegible] *used to mean the angular* [illegible]

The application of these rules to the various muscle paralyses taken in detail is as follows:—

Given a diplopia which increases in one direction we have—

A.—HORIZONTAL DIPLOPIA.

1. Increasing towards the *right*:—
    - (*a*) Image formed by the right eye further to the right: *Right External Rectus.*
    - (*b*) Image formed by the left eye to the right: *Left Internal Rectus.*
2. Increasing to the *left*:—
    - (*c*) Image formed by the left eye to the left: *Left External Rectus.*
    - (*d*) Image formed by the right eye to the left: *Right Internal Rectus.*

B.—VERTICAL DIPLOPIAS.

[illegible]
[illegible] ected.
[illegible] up and to the right than up and to [illegible] rior Rectus.

(*f*) Separation greater up and to the left than up and to the right: *Right Inferior Oblique.*

2. Left eye's image above:—
An elevator of the left eye affected.
    - (*g*) Separation greater up and to the left than up and to the right: *Left Superior Rectus.*
    - (*h*) Separation greater up and to the right than up and to the left: *Left Inferior Oblique.*

[illegible] wards.
[illegible] w:—
[illegible] eye affected.
[illegible] down and to the right than down and to the left: *Right Inferior Rectus.*

(*j*) Separation greater down and to the left than down and to the right: *Right Superior Oblique.*

2. Left eye's image below:—
A depressor of the left eye affected.
    - (*k*) Separation greater down and to the left than down and to the right: *Left Inferior Rectus.*
    - (*l*) Separation greater down and to the right than down and to the left: *Left Superior Oblique.*

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Benign Tumours (Fibroma, Myoma, Lipoma) Encapsuled in the Wall of the Stomach.—Some Cases of Gastric Surgery.

A MEETING of this section was held on June 8th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Mr. WALTER G. SPENCER read a paper on Benign Tumours (Fibroma, Myoma, and Lipoma) Encapsuled in the Wall of the Stomach. He said the connective-tissue tumours of the stomach were commonly sarcomata. There were, however, exceptions to that general statement: a benign encapsuled growth, a fibroma, myoma, or lipoma, might increase to a considerable tumour, and yet could be removed without damage to the stomach. These benign growths had been mistaken for sarcomata and an excessive operation had been done; when left alone, such tumours had caused death by pyloric obstruction, or by ultimately becoming malignant. A case under Mr. Spencer which occurred in a female, aged 46 years, was similar to a tumour of the stomach described by Morgagni. The patient was first seen by Mr. H. G. Barling, who discovered the tumour and distinguished it from the kidneys, which were both moveable in the horizontal plane. When drawn out through the abdominal incision the appearance was that of a perfectly normal stomach containing a soft body of the size and shape of a large kidney. The stomach cavity was quite normal, but the mucous membrane of the posterior wall was pushed forwards, yet was freely moveable over the tumour, which had grown in the submucous tissue. The tumour was easily shelled out and proved to be a dense fibroma of the shape and size of a large kidney, weighing 200 grammes, or 7 ounces. The patient recovered well, and three and a half months after was fit to resume her occupation. Mr. Spencer also showed a museum specimen of a precisely similar tumour, only smaller, the size and shape of a small sausage. But it was placed in exactly the same position, with the convexity downwards and the concavity close to the lesser curvature. It also during life formed a freely moveable abdominal tumour which the surgeon took for an intussusception and cut out the tumour along with the middle part of the woman's stomach. Finding out what he had done, he had to reopen the abdomen to correct the suturing, but the patient died. The tumour was shown *in situ* and was seen to be situated in the submucous layer, encapsuled and separable from the mucous and muscular coats. Under the microscope it had the structure of a myoma or fibromyoma. Reference was made to other cases of encapsuled and pedunculated benign tumours of the stomach; also to specimens in the Museum of the Royal College of Surgeons of England from the horse and cod-fish. Mr. Spencer, in conclusion, said that although it was impossible to diagnose such tumours except at the time of operation, yet benign tumours, either sessile or encapsuled, or pedunculated and easily detached, could be successfully removed without excising any portion of the stomach.—Mr. L. A. BIDWELL said it was interesting to note that a tumour of the stomach might be mistaken for a moveable kidney and described a case in point. He raised the question whether benign tumours ever became malignant.—Dr. H. MACNAUGHTON JONES remarked that malignant degeneration was observed in uterine myomata.—The PRESIDENT suggested that benign tumours became malignant, not from degeneration but from invasion from without.—Mr. SPENCER, in replying, pointed out that the question of benign tumours becoming malignant really resolved itself into a question of terms. A tumour that from an ordinary surgical point of view might be described as benign, might, if submitted to minute histological examination, be found to contain malignant features.

Mr. E. STANMORE BISHOP read a paper entitled "On Some Cases of Gastric Surgery." He said that surgery, as applied to gastric disease, had of late years attracted much attention. The proposal to treat surgically gastric ulcer and its results was comparatively recent, and all records of cases so treated were valuable, whilst the outcome had been, as a rule, so satisfactory that many previously looked upon as incurable or neurotic had been subjected to at least exploratory operations with a view if suitable to more definite procedures. Those explorations had resulted in the discovery of some conditions which were to a certain extent unexpected but which had proved amenable to surgical skill, such, for instance, as hour-glass stomach or early carcinoma, whilst experience had shown that gastric or duodenal perforations were, if attended to without loss of time, by no means the hopeless accidents they were once considered. Of partial gastrectomy there had been six cases. In all, operation was not sought until a well-marked mass was present which could be felt, and in two cases seen. The lump varied in size from a celluloid ball to a tangerine orange. The patients were two males and four females, their ages ranged from 38 to 57 years. All the patients were in very poor condition and had become emaciated; probably that accounted in large measure for the mortality—four out of six. Two survived for a period of 10 and 12 months respectively, but died ultimately: from certain recurrence in one case and from exhaustion with probable recurrence in the other, but that was not verified post mortem. The operation performed in each case was that of Billroth with end-to-end union, and that was followed in two cases by leakage at the angle between the vertical and circular sutures. In all great difficulty was experienced with the clamps. The later method of closing both openings completely and finishing with gastro-enterostomy evidently yielded better results, and was the measure which would probably be adopted generally in future. In the *Annals of Surgery* last year Mayo called attention to a triangular fold of peritoneum descending in certain cases from the duodeno-jejunal angle and losing itself on the jejunum and advised its removal. It would also be in the memory of all abdominal surgeons that a discussion arose some months since as to the correct line of apposition between the two viscera. Might it not be that that fold indicated the proper angle at which the united jejunum should lie, and that so far from removal it should be welcomed as an additional means of strengthening and protecting the line of union? In two of his cases it was observed and used for that purpose. The result was good, and in the later cases the angle so indicated had been followed as nearly as possible. Another point to which he had as yet seen no reference was the peculiar naked-eye appearance of the first seven or eight inches of the jejunum; that gut, which was the part desired for anastomosis, looked sodden, it had not the polished surface of the rest of the small intestine and was covered by a number of minute eminences; it might contain putty which had been compressed in places, so "moulded" was it. Of course, the surgeon relied mainly upon the fact of its emergence from the duodeno-jejunal opening, upon its anatomical position in fact, to assure himself that it was the coil required, but that was a confirmation which supplied additional certitude and was therefore welcome. He was not sure that that was always the case, but he had seen it in so many that he should confess to a feeling of doubt and uneasiness if it were not recognisable. Another point was the value of the symptom of hunger-pain as a differentiator between gastric and duodenal ulcers. This symptom undoubtedly had great significance, and was of much importance in the differential diagnosis, but he ventured to hint that that differential value might be somewhat exaggerated. In two or three of his cases in which duodenal ulcer was demonstrated at the operation that symptom was absent, whilst in a case sent to him by a well-known physician with a confident diagnosis of duodenal ulcer, based upon its presence, no duodenal ulcer was found, but a typical saddle-shaped ulcer of the lesser curvature of the stomach was present. The operation itself appeared to act very much in the same way with reference to the passage of food through the alimentary canal as perineal section did with regard to the passage of urine through the urethra when a stricture was present; the stricture in that case being at the pylorus, at first all the contents passed through the new opening; the stricture being thus allowed to rest, if not cancerous, slowly yielded; some content began to find its way along the normal route, then more and more, less and less passing through the artificial opening, until at last the normal route became again the only one. Whether the new [illegible] totally closed, [illegible] far appear to be [illegible] tended in that direction, the x-ray evidence he had been able to obtain seemed to show very definitely.—After Mr. BIDWELL, Mr. C. P. CHILDE, and Mr. SPENCER had spoken, Mr. STANMORE BISHOP replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Eye-Strain.—Pharmacology of Ergot.

A MEETING of this society was held on June 2nd, Dr. JAMES RITCHIE, the President, being in the chair.

Mr. GEORGE A. BERRY opened a discussion in a communication entitled "Critical Remarks on the Symptomatology and Causes of so-called Eye-strain." After referring to the vagueness of the term he said that popularly "weakness" [illegible] intolerance of [illegible] headache ind[illegible] hand, was a term originated by the medical profession and he did not know of it as distinct from asthenopia; indeed, he preferred the latter term as it was associated with a generic diagnosis. He thought that the bearing which eye conditions had in causing headache had been exaggerated. When there was hypermetropia, or astigmatism, or an absence of complete lateral parallelism of the axes of the two eyes, it did not follow that the deviations from the normal accounted for the patient's complaints as they were too readily assumed to do. Speaking generally, the symptoms which in his opinion indicated eye-strain were due either to irritations of the superficial nerves in the conjunctiva and cornea or to the use of the eyes under conditions which called for a strained [illegible] alone. In other cases the headache might be looked upon more as the effect of the cerebral effort which was required to dissociate nerve impulses. In almost all cases of eye-strain there was also an individually variable element to be considered—namely, the neurotic element. Equal sources of irritation produced different degrees of pain in different individuals or in the same individual at different times. Thus, in health an effort might be made without the conscious appreciation of its being an effort, while in ill health it might be associated with asthenopia. Thus often during convalescence from acute illness, discomfort or pain in the eyes or headache might be experienced for the first time. The most frequent causes of conjunctival and corneal irritation were lid pressure, exposure to strong illumination, and gout. Lid pressure was very often induced by astigmatism, especially if this was one in which the horizontal meridian of the cornea was the most highly curved (as happened in 20 per cent. of astigmatic eyes), when an unconscious effort was made to correct it by pressing the lids on the eye. Generally this could only be done by frowning. The pressure induced irritation of the cornea leading by summation to the sensation of frontal strain and headache. Most people who have walked in the glare of the sun have experienced this headache as a result of the frowning and semiclosure of the eyes. Many astigmatics have found out that their vision can be improved by pressing the finger-tip on the eyeball. The ophthalmometer revealed in many cases the change which lid pressure produced on the cornea. The headache induced by lid pressure arose mainly when the eyes were focussed on near objects. Lid pressure was only resorted to in the lower degree of astigmatism because headaches did not accompany the higher degrees of this affection. Asthenopic symptoms from the superficial irritation caused by strong illumination were very common and were due to the effect of the ultra-violet rays. The eyes were usually protected from such rays by being directed to the green of grass or trees which absorbed the rays. The symptom set up by such strong light as sunlight, reflection from white paper, incandescent gas or electric light was not generally headache but smarting of the eyes when reading and inability to continue reading for long. The symptoms quickly disappeared when the patient was kept in a darkened room, but such treatment was both unnecessarily irksome and even hurtful. All that was necessary was to protect the eyes from the rays by special glasses, the best of which was called "euphos," but "London smoke" glasses afforded a sufficient protection and allowed the patient to live in sunlight. When there was astigmatism the use of cylindrical glasses became necessary but they were only required for reading or other near work if headaches were present. Another form of eye-strain was technically called asthenopia accommodativa. The most frequent cause of this kind of headache was hypermetropia and it was aggravated by reading with insufficient light. Reading in bed was often hurtful because the illumination was obtained from a single feeble candle. Myopic conditions were easily recognised, and hence the symptoms complained of could be treated. Early and full correction for reading until after the age of full growth was now generally recognised to be right. In what has been called asthenopia nervosa the patients were, in fact, hysterical and treatment by suggestion was advisable. Mr. Berry had found the subcutaneous injection of sterilised water over the eyebrows was most efficacious, and the use of dark glasses must be forbidden. Not more than three or four injections should be given.—Dr. GEORGE MACKAY said that the personal equation in eye-strain was remarkable. Some individuals with very marked errors of refraction never suffered from headache, while in other cases with very slight errors the disability owing to headache was intense. The employment of a very weak prism often afforded remarkable relief.—Dr. W. G. SYM said that an endless number of diseases, including sterility, diabetes, and appendicitis, were supposed by some to be due to eye-strain. He thought that Mr. Berry had made too much of the lid-pressure theory.

Dr. ALEXANDER GOODALL read a paper entitled "A Pharmacological Estimate of the Value of Commercial Samples of the Liquid Extract of Ergot with Notes on Ergot Standardisation." He said that in the case of some drugs whose active [illegible] a chemical standard was laid down [illegible] where no che[illegible]tion gave no guidance. It had been found, however, by many firms of manufacturing chemists that it was in their interest to employ a pharmacological test for some of their products, and in the case of certain substances there now existed ample data to afford standards. Well-known examples were the tinctures of digitalis, strophanthus, and squill, and the preparations of adrenalin and cannabis indica. The position regarding ergot was different. Its therapeutic effects were notoriously uncertain, and its chemistry was in a state of chaos. There was no general agreement regarding its pharmacological action, and there were no very satisfactory data to afford guidance in attempting to fix a pharmacological standard. Added to all this was the fact that ergot preparations tended to lose their activity very rapidly. Among the methods of standardisation employed were: (1) depth of blue produced in the cock's comb; (2) the effect on the blood pressure in pithed or in anæsthetised animals; (3) the reversal of the effects of adrenalin; and (4) the effect upon the isolated uterus. The first method consisted in injecting fluid extract of ergot into fowls or feeding them with an ergot preparation. If the preparation was active the comb and wattles became blue and cold. The method was not a certain one. There was evidence that toxic effects and even gangrene might be caused without any effect being necessarily produced on the contraction of the vessels or visceral muscle elsewhere. The second method consisted in injecting a fluid preparation intravenously and noting the effect on the blood pressure of a pithed or anæsthetised animal. In this way it was quite possible to increase the blood pressure in a cat by 20 or 30 millimetres of mercury. The third method was introduced by Dale, who said that he had found it apply in particular to a base which he had isolated and called ergotoxin. Stated briefly, the method depended upon the fact that if adrenalin be injected into an animal during the rise of pressure caused by ergotoxin it would cause a fall of pressure, but Dr. Goodall had not been able to obtain satisfactory results with preparations stated to be standardised by this method. The fourth method depended on the effect of ergot in Ringer's solution on the isolated uterus, and had been commended as an excellent means of standardisation. Dr. Goodall at first considered that the effect upon the blood pressure seemed to be the simplest and most accurate. Observations were accordingly made upon rabbits and cats under full anæsthesia by ether. The readings were taken from the carotid artery. The injections were made into the jugular vein. The results have been classified in three series—namely: (1) the effect on the blood pressure produced by special samples of ergot; (2) the effect on the blood pressure produced by ordinary commercial samples of ergot; and (3) combined observations of the effects produced on the blood pressure and on the uterus. The observations in Series 1 were made with samples submitted to Dr. Goodall by manufacturing chemists to be tested physiologically, so that these samples were probably made from carefully selected ergot. In every case there was a fall of blood pressure succeeded by either a return to normal or a rise above it. The results given by the last 17 specimens showed an average fall of 39·4 millimetres of mercury, followed by an average rise of 20·5 millimetres above normal. As regards pressor action—i.e., the subsequent rise above normal—five specimens had no effect and five caused a rise of 30 or more millimetres. In other words, 70 per cent. failed to cause a rise of 30 millimetres and 41 per cent. failed to cause a rise of 20 millimetres. In Series 2 use was made of samples of liquid extract of ergot obtained from well-known houses in London, Edinburgh, and elsewhere. The collective result was that 76 per cent. of these commercial samples failed to raise the blood pressure 20 millimetres of mercury. In Series 3 the combined effects on the blood pressure and on the uterus were observed. Of the 21 samples employed, 14 caused a satisfactory contraction of the uterus in doses which did not necessarily raise the blood pressure, while four samples caused a slight contraction, and only three failed to affect the uterus. This means that 66 per cent. of the samples caused a well-marked uterine contraction, and that 85 per cent. caused a contraction of some sort. The most striking phenomenon of the three series was the absolutely constant fall of blood pressure which followed immediately upon an intravenous injection. It was stated by Dixon that this fall was due to impurities and that it did not occur if the ergot was injected subcutaneously. The question of the absorption of ergot did not come within their purview, but there could be no doubt that the pharmacology of ergot would remain unsatisfactory until a means of separating the depressor constituents had been discovered. The rise of pressure which followed the fall was not nearly so constant, but it might have been that in many experiments the depressor and pressor substances balanced each other. A sample of ergot which caused a rise of blood pressure also caused contraction of the uterus, but a sample which caused no rise of blood pressure might nevertheless cause a satisfactory uterine contraction. Samples of ergot might cause contraction of the uterus in smaller doses than were required to raise the blood pressure. Ergot therefore appeared to have a specific action on the uterus. Dr. Goodall considered that the effect on the blood pressure was a *satisfactory* pharmacological test as far as the prescriber was concerned. A fair standard was that a dose not greater than 20 minims injected intravenously should cause a rise of blood pressure of 20 millimetres of mercury in an anæsthetised animal weighing 1500 grammes. On the other hand, since 42 per cent. of the commercial samples caused contraction of the uterus without effecting a rise of blood pressure, the action on the uterus might be regarded as a more satisfactory test by the manufacturer, and in view of the almost exclusive use of ergot in uterine conditions might be considered sufficient by the prescriber.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—A meeting of the Obstetrical Section was held on May 21st, Mr. E. H. Tweedy, the President, being in the chair.—The President exhibited specimens of Fibroids with red degeneration, removed six weeks after delivery. The woman had been sent to him six months pregnant and with a large myoma. He kept her over two months in hospital. He induced labour at full term. The child was dead. On the third day her temperature and pulse rose, and on the fourth day the temperature reached 103° F. There was great tenderness of the abdomen and he became very uneasy about the case. He asked Sir William Smyly to see her in consultation on the fifth day with a view to immediate operation. Sir William Smyly advised postponement of the operation and the woman got gradually better. When her temperature became normal he removed the tumour by supra-vaginal hysterectomy. It showed in a very characteristic manner red degeneration, which was a disease that apparently very rarely occurred save in pregnancy. High temperature was a constant symptom of red degeneration, and this he thought might arise apart from a germ invasion and be due to absorption of toxic matter from the degenerating myoma.—Dr. R. D. Purefoy said that the change noticed in one of these tumours was one of the least common forms of degeneration and one of which they knew least. He was not quite convinced that the temperature was due to the red degeneration. He was inclined to think that it was connected with a certain degree of localised sepsis.—Dr. H. Jellett said he was watching a patient who came to him six months pregnant with a large myoma below the fœtus, filling the pelvis. The patient had been going on very well since. In such a case, where there was a large myoma on the posterior wall of the uterus, filling the hollow of the sacrum, and in which the cervix was jammed above the symphysis, he would like to know how long Mr. Tweedy would allow her to remain in labour. Sometimes tumours that were firmly impacted did get drawn up, but in his case it seemed rather hopeless to expect the tumour to do so.—Dr. R. J. Rowlette said there were certain points about red degeneration which were fairly fixed. It was commonly found associated with pregnancy, and seldom in other conditions. In almost every myoma associated with pregnancy which he had seen there had been more or less red degeneration. It was certainly a necrotic change of some sort, as the tissue failed to stain. In pregnancy the entire tissue of the uterus was in a highly vascular condition, and something interfering with the blood-supply, causing stasis in the veins, might cause a diffusion of blood pigment. There was no doubt that in some cases the red degeneration might give rise to temperature, as it was liable to be affected by septic or putrefactive organisms.—The President, in reply, said the fibroids were chiefly situated on the fundus, but also encroached on the lower uterine segment. It was only when he became convinced that the growth had undergone degeneration that he determined not to let the patient run the risk of another pregnancy. He thought Dr. Jellett's case was plain sailing. His patient should not be allowed even to fall into labour. He should calculate the time of full term and perform Cæsarean section. After removing the child it would be easy to remove the uterus. The myoma was almost certain to degenerate if she was allowed to fall into labour. He thought there was a toxin that could raise the temperature apart from germ invasion.—Dr. Purefoy read a paper on Some Pathological Conditions of [illegible] paper entitled [illegible] complicated by [illegible] and others dis[illegible]

Reviews and Notices of Books.

Further Advances in Physiology. Edited by Leonard Hill, M.B. Lond., F.R.S. With diagrams. London: Edward Arnold. 1909. Pp. 440. Price 15s. net.

This volume is the sequel to "Recent Advances in Physiology" by the same editor, and deals with certain branches of the science other than those dealt with in that volume. The aim of the editor and his coadjutors has been to record their views on certain selected subjects which have a particular application to pathology and clinical medicine—e.g., problems concerning the circulation and respiration, the neuro-muscular system, and vision. To each subject is appended a bibliography of recent works on that subject.

Professor Benjamin Moore writes on the Equilibrium of Colloid and Crystalloid in Living Cells (pp. 1–33). It is a dissertation on chemico-physical matters, including a discussion of that excessively complex physico-chemical aggregate called protoplasm or bioplasm and its essential constituents the proteins. The importance of the inorganic ions for cell life and activity is set forth. The relation of nutrient fluids to the heart beat is admirably discussed, and the paramount importance of ions of the inorganic salts which, while they have a loose union with the proteins, possess such freedom of movement that they give to the solution in which they exist many of the more important physico-chemical properties of a saline solution. The author concludes "that neither osmosis nor any other physical hypothesis which leaves out the peculiar and varying chemical constitution of bioplasm can yield an explanation of absorption, secretion, or excretion," and that "the unstable unions between bioplasm and dissolved substances furnish the key to many of the intricate problems both of physiology and of practical medicine."

Dr. Martin W. Flack's essay on the Heart (pp. 34–71) deals with its histology and morphology and with the nervous elements of the vertebrate heart. The heart musculature is now known to be of the nature of a syncytium. The *a.-v.* bundle, of course, receives special attention. "The evidence that the *a.-v.* bundle is the sole passage of conduction is tolerably strong" (p. 61). The peculiarities of cardiac muscle as contrasted with skeletal muscle are set forth in detail. The relative merits of the myogenic and neurogenic theories of the heart beat are critically examined, but Engelmann's terms, "chronotrop," "inotrope," do not seem to be introduced, while in connexion with the revival of apparently dead hearts after many hours we do not find the name of Kuliabko. There is also a careful study of the heart *in situ*.

"Pulse Records in their Relation to the Events of the Human Cardiac Cycle" (pp. 72–111) are reviewed by Dr. Thomas Lewis. The author insists on the value of graphic curves taken simultaneously from different pulsating parts. The venous pulse in man and animals is fully studied, and a minute study is made of the auricular pressure curve and the jugular pulse tracing. Wenckebach on occasion is printed as "Wenchebach" in this essay.

The editor's chapters on "The Vascular System and Blood Pressure" (pp. 112–181) are both interesting and controversial. In Pawlow's laboratory the establishment of what is called Eck's fistula—i.e., joining the portal vein and vena cava—was the prelude to the more heroic work of Carrel, Guthrie, and others in America, which has opened up a new field in experimental work. The carotid has been stitched by Carrel to the external jugular vein, and the circulation in the thyroid gland reversed with no ill consequences. A length of the carotid artery of a dog has been kept in normal saline solution at 32° F. for 20 days and then successfully transplanted in the course of the abdominal aorta of a young cat, and on the seventy-seventh day the animal was in perfect health. He who wishes to read the Romance of Surgery will find it in the *Journal of Experimental Medicine.* The experiments were made at the Rockefeller Institute, and of Carrel's paper on "Transplantation in Mass of the Kidneys" a *résumé* with illustrations is given by Dr. Hill.

Dr. Hill also recounts fully the recent experiments on the contractility and elasticity of arteries, of arterial, venous, and capillary pressures in man, and the methods of measuring them; and especially does he dwell on the factors that cause increased tension in organs enclosed in capsules, which leads him to the consideration of glaucoma and intracranial and other pressures. He finds that a pressure of from 10 to 20 millimetres of water are sufficient to overcome the capillary pressure in the arm placed at the heart's apex level (p. 142). We would call attention to the importance attached by Dr. Hill to muscular movements in connexion with the circulation, and we can do so best by quoting his own words:—

> The function of the heart is to drive the blood into the capillary bed; [illegible]

The effect of mental work on blood pressure and the importance of muscular exercise in the cure of irritable dyspepsia of brain-workers are considered. Dr. Hill then deals drastically with the present filtration hypothesis relating to lymph formation, œdema, and dropsy. Plethora, hydræmia, hyperæmia, shock, and collapse are next considered. The whole essay is worthy of careful study.

Dr. Arthur Keith writes an excellent monograph on "The Mechanism of Respiration in Man" (pp. 182–207). It is a telling example of how the study of what is apparently common-place in matters of anatomy may be made to shed new light on physiological problems. The author gives a summary of 16 points with which he deals; among his conclusions being that:—the expansion of parts of the lung are unequal, and the most expansible parts are the infundibula; the bronchial muscle regulates the tension of the infundibular air; the roots of the lungs are not fixed as is generally held; the great fissure of the lung is of functional importance; expiration is controlled by muscular action, and the diaphragm acts as a piston. We notice the author uses the term "Rontgen" instead of "Röntgen."

Dr. M. S. Pembrey's chapters on the Physiology of Muscular Work (pp. 208–257) are both interesting and practical. He is right in insisting that we ought to study the muscular activity as a whole as regards speed, endurance, and strength, *as in athletes, and make* more use of the results of trainers of men and animals. The effects of muscular work on the different functions of the body are fully considered. Some chapters on the Physiology of Nerve, by Dr. N. H. Alcock (pp. 258–283), will appeal more to the physiologist than to the practitioner; still the remarks on regeneration of nerves will have a special interest for the latter. We should like to have seen a fuller account of Head's work on section of nerves. We notice that the word "zincatine" is retained, and the term a "wave of zincatinity" is used.

Perhaps the most "revolutionary" chapter of all is that of Dr. J. S. Bolton on Recent Researches on Cerebral Localisation (pp. 284–350). A full account of the significance of cerebral lamination is given, including the superb work of Campbell, Brodmann, and others. The functions of the different cell laminæ are discussed, and the use of histology as a method of cortical localisation. Full credit is given to the researches and generalisations of Flechsig; nor is the early work of Bevan-Lewis and Clarke and the later work of John Turner forgotten. One of Dr. Bolton's most interesting chapters is that on the higher functions of the cerebrum. The classical views of aphasia and the time-honoured localisation of the motor speech centres in Broca's convolution have recently been assailed by Marie and Monakow. Physiologists and physicians should read and ponder well this comparison and critical dissection of the older and newer views on aphasia. They would do well also to study the discussion on language and on "alteration of personality." The Studies in Special Sense Physiology (pp. 351–425) by Mr. M. Greenwood deal with (1) visual adaptation, and (2) colour-blindness. The principles of the two modern theories of vision are considered and criticised; there is also an interesting historical introduction, including the speculations of the Greek philosophers on vision.

We cordially commend this work alike to physiologists and to medical men. It is at once scientific and suggestive, while the problems with which it deals so successfully are amongst the most interesting and practical that can engage the attention of all true students of medicine.

A System of Medicine by Eminent Authorities in Great Britain, the United States, and the Continent. Edited by William Osler, M.D. Oxon. and McGill, F.R.S., Regius Professor of Medicine in the University of Oxford, Honorary Professor of Medicine in the Johns Hopkins University, Baltimore; assisted by Thomas McCrae, M.D., F.R.C.P. Lond., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Vol. V., Diseases of the Alimentary Tract. London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 903. Price 30*s*. net.

In this volume of 903 pages is contained a series of monographs giving a most complete and erudite account of the diseases of the alimentary tract.

The first chapter is written by Dr. C. G. Stockton (Buffalo) and is headed Introductory Discussion on the Diseases of the Digestive Apparatus. Certain critical relations are described that may exist between disturbed physiological activity and structural changes as expressed in morbid processes. Dr. Stockton points out that digestion is frequently looked upon as the function of an extensive and complicated apparatus, but it is so intimately related with the functions of other parts of the body that it is difficult to draw lines of precise limitation beyond which it can be said that digestion has no part and from which it receives no reciprocal activity. The digestive apparatus is commonly spoken of as including the alimentary tract and those important glands which contribute specific secretions to the advancement of digestion; but as absorption and assimilation, on the one hand, and the formation and withdrawal of catabolic and waste products, on the other, are so immediately related to the preliminary digestion, it is impossible to form a clear conception of the diseases of the digestive organs without taking into consideration the state of other and contributing parts of the organism. The author then draws attention to some physiological points in what he terms the interrelation of digestive functions. Common experience teaches that the mental state and the sense of taste in some unknown way affect the primary digestion. Thus worry induces leanness, and happiness favours the opposite condition, in a measure independently of the amount of food taken. Further, the digestive secretions and the motor activity of the stomach and intestine are excited by proper psychical stimulation, and some of them inhibited, others over-excited, by distress. Several similar examples are given of the effect of other organs on the digestive organs, indicating the necessity of taking a broad view of the whole mechanism of the body when digestion is at fault.

Chapter II. is occupied with a consideration of diseases of the mouth and salivary glands, the author being Dr. D. Riesman (Philadelphia). A good account is given of the various affections of the mouth, especial attention being given to leukoplakia.

Diseases of the œsophagus are described by Dr. T. McCrae (Baltimore). Carcinoma of the œsophagus is considered at length and the frequency with which perforation is met with is noted. This complication may take place into different organs or areas, depending upon the site of the growth, but in by far the greatest number the ulceration occurs into the large air passages, the larynx, trachea, or a bronchus; apart from these situations it may occur into the mediastinal tissue, the pleura, the lung, or even, although a rarity, into the pericardium.

Functional diseases of the stomach are considered by Dr. Julius Friedenwald (Baltimore). The conditions of hyperchlorhydria, gastrosuccorrhœa, gastromyxorrhœa, gastralgia nervosa, achylia gastrica, and neurasthenia gastrica are described in an admirable manner. The symptoms and diagnosis are carefully discussed, and numerous useful hints are given in regard to therapeutics. Diet naturally holds an important place in the treatment of all these conditions, and the nature of the food which should be given is accurately and minutely laid down. The drugs which may prove useful are also indicated. In speaking of the preparations which may be employed in hyperchlorhydria Dr. Friedenwald remarks of the alkalies that may be useful in neutralising the excess of acid, that the bicarbonate of soda, calcined magnesia, magnesia carbonate, calcium carbonate, and the phosphate of soda are most frequently prescribed, and that calcined magnesia has an advantage over bicarbonate of soda, as the former neutralises four times as much acid as the latter; it has the additional advantage that it is distinctly laxative, and is therefore especially useful when constipation is present.

Dr. C. F. Martin (Montreal) is responsible for the chapter on organic disease of the stomach. Commencing with gastric and duodenal ulcer, he dwells at length on the pathogenesis of the former, but arrives at general conclusions only—namely, that gastric ulcer occurs wherever gastric juice flows, that the process in its earliest stages is essentially a necrosis, and that healing is prevented in some way by the action of the gastric juice. He also discusses the relationship of the circulatory system to this disease, but without expressing any definite opinion. He seems to indicate that neither embolism, hæmorrhagic erosions, nor submucous hæmorrhages satisfactorily explain the formation of ulcer. In regard to the neuropathic theory which has been advanced, Dr. Martin believes that beyond lowering the resisting power of the tissues of the stomach and also inducing hyperacidity, there is little connexion between injury of the nervous system and production of gastric ulcer.

The pathology of cancer of the stomach is fully described. It is pointed out that the growth is nearly always primary, secondary involvement being rare. Most practitioners will agree with the statement that there is no one pathognomonic sign of cancer in this site. The diagnosis must be made from the symptom and sign complex. Reference is naturally made to the secretory power of the stomach in cases of malignant disease of that organ, for it has been asserted that absence of hydrochloric acid is characteristic of that condition. Dr. Martin, however, points out that the absence of this acid is but one sign and of partial importance only, for the same phenomenon occurs in gastric neuroses, catarrh, and atrophy of the stomach, and also in the course of fevers and constitutional disturbances. On the other hand, he remarks that although the presence of lactic acid is not pathognomonic of cancer and may be present in intestinal obstruction, sometimes even in benign pyloric stenosis and other conditions, nevertheless its early appearance in cancer, together with a diminution of the total acidity even before any signs of stenosis, is very important.

Diseases of the intestine are described by Dr. Alfred Stengel (Philadelphia). A full and complete account is given of the chief intestinal affections, whilst brief reference is made to the less common ones, such as sprue, epidemic gangrenous proctitis, and others. One of the most striking features of this portion of the work is the manner in which the differential diagnosis of the principal diseases is discussed. The diagnosis of abdominal affections is often a matter of great difficulty, and Dr. Stengel's remarks are worthy of careful study. Much useful information will be derived by reference to them and some of the remarks are quite illuminating.

Dr. H. D. Rolleston (London) writes on diseases of the peritoneum. He makes some interesting observations on the natural resistance of the peritoneum against disease. He points out that the defensive powers of the membrane consist in (1) the great absorptive power of the peritoneum, by means of which invading organisms are carried away before they can multiply *in situ*, produce toxins, and so set up inflammation (it should, however, be noted that this absorptive power may lead to a general infection or toxæmia); (2) the phagocytic action exerted by endothelial cells, polymorphonuclear and other leucocytes; and (3) the bactericidal and antitoxic power of the peritoneal fluid. The section on subphrenic abscess will be found interesting. 11 causes of simple subphrenic abscess are tabulated, appendicitis being set down as the most frequent. The condition is one which is not infrequently missed and any information upon the physical signs that might help us in diagnosis is welcome.

A chapter by Dr. T. R. Brown (Baltimore) is devoted to a description of splanchnoptosis. The author considers this term preferable to enteroptosis, since the latter word simply means descent of the intestine, whilst the former may be taken to signify descent of any or all of the abdominal viscera. In describing the displacement of the individual organs special terms are used, such as nephroptosis, gastroptosis, and so on. Dr. Brown also remarks that in the earlier days nephroptosis, being much more easily recognised, was regarded as the most important feature, and to it were ascribed the protean symptoms often met with, while later investigations with better methods of diagnosis have shown that the displacement of the kidneys is usually associated with the displacement of the stomach, intestines, &c., and that many of the symptoms originally ascribed to floating kidney are in reality referable to displacement of other organs. This statement may perhaps explain the failure of operative measures which sometimes follows attempts made to give relief to floating kidney.

Diseases of the pancreas are considered by Dr. E. L. Opie (New York). The interesting condition, acute hæmorrhagic pancreatitis, receives full attention.

The last chapter in the book is by Dr. A. O. J. Kelly (Philadelphia) and deals with diseases of the liver, gall-bladder, and biliary ducts. An excellent account is given of cholelithiasis, the remarks on treatment being particularly worthy of attention.

We have perused this volume with pleasure. Much of the information which it contains is most valuable and we can cordially recommend the work to our readers. The subjects with which it is concerned are constantly met with in the ordinary course of practice, and many present great difficulties in the way of diagnosis and treatment. The principal feature of the work is the practical manner in which the authors of the various articles have dealt with the conditions which they have described. Theoretical considerations have not been neglected, but the symptomatology, diagnosis, and treatment have invariably been most fully and satisfactorily discussed; hence as a work of reference this volume will prove especially valuable.

Manual of Diseases of the Ear, Including Those of the Nose and Throat in Relation to the Ear. By THOMAS BARR, M.D. Glasg., Lecturer on Diseases of the Ear, University of Glasgow; and J. STODDART BARR, M.B., Ch.B. Glasg., Assistant Lecturer on Diseases of the Ear, University of Glasgow. Fourth edition, with three coloured plates and six illustrations. Glasgow: James Maclehose and Sons. 1909. Pp. 477. Price 14*s.*

WE have already had reason, when reviewing the previous editions of Dr. Thomas Barr's work, to speak of it in laudatory terms, and we have great pleasure in saying that we have still more reason to speak well of this volume. In the chapter on General Symptomatology there is a fairly full dissertation on the disturbances of equilibrium, and in referring to this symptom further on in the book it is stated that more experience is necessary with regard to Bárány's experiments. Although these experiments are alluded to, there is no detailed instruction given as to their employment, an omission which we regret, and trust that it will be remedied in the next edition. Otomassage is introduced for the first time in this edition—that is to say, if by that term nothing more is understood than the results obtained by the use of Delstanche's pneumatic tractor. Wilde's incision is still recommended in suitable cases; and although it must be admitted that this is not the usual teaching, yet it is a point upon which it is more than probable that there would be justifiable diversity of opinion. The portion of the book devoted to operations is extremely clear and well written. The section on Diseases of the Nose and Throat in Relation to Diseases of the Ear is somewhat altered, but not materially so; while that on Labyrinthine Suppuration has been very carefully brought up to the present date. As an addition in this issue three plates have been inserted each showing 15 coloured drawings of ear drums, with a detailed description. These will be extremely useful to students, some of them being particularly fine examples. The book has lost nothing by the inclusion of Dr. Stoddart Barr in the editorship. It is a splendid text-book and admirably written, and the rapidity with which successive editions appear shows well its popularity.

La Renaissance de l'Ophtalmologie. By Dr. JULIUS HIRSCHBERG, *Professor of Ophthalmology in the University of Berlin.* Translated from the German by Dr. DANIEL VAN DUYSE, Professor of Ophthalmology in the University of Ghent. With 12 figures in the text and seven plates. Leipzig: Wilhelm Engelmann. 1908. Pp. 147. *Price 6 marks.*

THIS brochure, dedicated to the Academy of Medicine of Paris by the author and translator, comprises the section on the renaissance of ophthalmology in the eighteenth century in the second edition of the great Graefe Saemisch Handbook of Ophthalmology. It is fitting that the history of the period which is distinguished by the pre-eminence of Daviel, the originator of extraction as the mode of election for the treatment of cataract, should appear in French guise. Moreover, it is a period of consuming interest for ophthalmologists, hardly less for Englishmen than for their French *confrères*, and many who find it difficult to read German will be grateful to Dr. van Duyse for his admirable translation. It lacks the bibliographies of the original and some of the notes; in the copy sent to us for review the last plate is also wanting.

The work is divided into three chapters—on the controversy as to the nature of cataract, on the operation for artificial pupil, and on the extraction of cataract. It is shown that Werner Rolfinck established anatomically the seat of cataract in the lens in 1656, thus confirming the opinion and perhaps the direct observation of François Quarré, a Parisian surgeon. At this period the lens was regarded as the seat of vision, and it was utterly heterodox to imagine that sight could be retained if it was injured or diseased. Hence a great controversy arose, the majority of surgeons retaining the old view that cataract was an opacity in front of the lens, which at that time was thought to be situated much farther back in the eye than is actually the case, the intervening space forming the posterior chamber. The struggle reached its climax in the early part of the eighteenth century, when a French surgeon, Brisseau the younger, re-discovered the truth and published it to the world in a small treatise on cataract and glaucoma in 1709. The famous Antoine Maitre-Jan subsequently made the same observation, apparently independent of Brisseau, since he does not mention his name. The first engagement in the campaign took place in the French Academy of Sciences and was notable for the conversion of Saint Yves. The greatest opponent of the theory, however, was the extraordinarily clever and unscrupulous Thomas Woolhouse, a man whose only rival in brilliancy, audacity, and charlatanism in the early history of ophthalmology is his compatriot Taylor. In France, besides Saint Yves, the new view was supported by Morand and François Pourfour du Petit, whilst strenuous adherents were found elsewhere—Heister, the illustrious anatomist and surgeon, in Germany; the not less illustrious Boerhaave in Holland; Valsalva, Morgagni, Benevoli, and Cocchi in Italy; and Cheselden, not to mention John Taylor, in England.

Cheselden, one of the glories of St. Thomas's Hospital, has left his mark on ophthalmology as the inventor of the operation for the formation of an artificial pupil. His first communication appeared in the Philosophical Transactions of the Royal Society in 1728, and dealt with the division of the "contracted" iris with a needle. Further observations on the subject were published in the fourth and subsequent editions of his anatomy. Cheselden and his pupil Sharp called the operation simply "incision through the iris," but it soon obtained the more dignified, if also more pedantic, name coremorphosis (pupil-formation). It is almost with regret that the honour of suggesting the procedure must be attributed to Woolhouse (1711). The second method of establishing an artificial pupil, by the excision of a cuneiform segment of the iris—iridectomy—is due to Joseph Beer of Vienna (1798). Even the production of an iridodialysis was advocated by Scarpa and others for the same purpose, but rapidly fell into disrepute. Iridencleisis, the incarceration of the iris in a corneal or scleral wound with a view to dragging the pupil to one side, was employed by Adams (1812), Himly, George Critchett, the elder Pagenstecher, and others. Patients on whom this operation has been performed are occasionally met with to-day, but unfortunately the eyes were liable to become inflamed and sympathetic ophthalmia not infrequently ensued.

The account of the introduction of extraction as the routine method for dealing with senile cataract will doubtless prove the most fascinating part of this record. It had been suggested by Steven Blankaart in 1668, and actually employed for lenses dislocated into the anterior chamber by Saint Yves and Petit in Paris in 1707 and 1708. The honour of introducing the operation for senile cataract and placing it upon a sound basis belongs without doubt to Jacques Daviel, whose first publication appeared in the *Mercure de France* in 1748. His chief publication was a communication to the French Academy of Sciences in 1752. Dr. Hirschberg and Dr. van Duyse have reproduced it in extenso, and ophthalmologists will read with profound interest this landmark in the history of their profession. In his earliest operations Daviel made a section which included the lower two-thirds of the cornea and followed the apparent corneo-scleral margin. The incision was commenced with a lance-shaped knife and completed with curved scissors. The flap was turned upwards with a spatula and the lens capsule opened with a needle. The lens was expressed by pressure with the finger on the lower lid. Later the section included only half the circumference of the cornea, and still later experiments were made with a triangular flap. The battle was not yet won. The new procedure demanded manipulative ability which every surgeon did not possess. A wave of reaction followed, abetted by Percival Pott and B. Bell of Edinburgh, though strongly opposed by Jonathan Wathen and James Ware amongst English surgeons. The final victory was ushered in by Joseph Beer, Frederick and Edward Jäger, Rosas, Fischer, Arlt, and Hasner, all members of the Austrian school: Sichel, a pupil of Frederick Jäger, carried it into France, where it was driven home by his pupil Desmarres. The subsequent history of the operation is too familiar to need recapitulation, dealing as it does with improvements of technique introduced by the modern school of ophthalmology which had its rise in von Graefe.

It will be gathered from our *resumé* that this book is one which every ophthalmologist will peruse with pleasure and profit, though it will be a matter for regret that English surgeons play no very creditable part in the story.

LIBRARY TABLE.

A Reference Handbook of Gynecology for Nurses. By CATHARINE MACFARLANE, M.D., Gynecologist to the Women's Hospital of Philadelphia. London and Philadelphia: W. B. Saunders Co. 1908. Pp. 150. Price 6*s.* net.—In this little book the authoress has attempted to set clearly before her readers the main facts in regard to gynæcological nursing which it is necessary for nurses to know. A short account is given of the commoner gynæcological affections, and then the preparation of a patient for an operation, the details of the duties of the nurse during the operation, and the after-treatment of the case are all considered. To help the memory illustrations are given of all the instruments required for the various operative procedures. The recommendations upon the whole are good and accurate, the author has evidently taken a good deal of pains to express herself clearly and succinctly, and the book should prove of value to those nurses for whom it is intended. English nurses engaged in this class of nursing may refer to it with advantage.

Aids to Obstetrics. By SAMUEL NALL, M.B. Cantab., M.R.C.P. Lond. Revised by C. J. NEPEAN LONGRIDGE, M.D. Vict., F.R.C.S. Eng., M.R.C.P. Lond. Seventh edition. London: Baillière, Tindall, and Cox. 1909. Pp. 193. Price 2*s.* 6*d.* net.—Dr. Nall's "Aids to Obstetrics" is too well-known a book to require much notice on our part. It has been of assistance to hundreds of students, and although as a rule we do not regard with favour cram-books of any kind, yet so long as a demand exists for them it is important that it should be satisfied so well as it is by this little book. In the production of this the seventh edition the author has secured the coöperation of Dr. Nepean Longridge, and the book appears to have been revised well and brought up to date.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by Sir Ray Lankester, K.C.B., F.R.S., with the coöperation of Adam Sedgwick, M.A., F.R.S., Sydney J. Hickson, M.A., F.R.S., and E. A. Minchin, M.A. With lithographic plates and text figures. London: J. and A. Churchill. New series, No. 211 (Vol LIII.), Part 3. May, 1909. Subscription per volume of four parts, 40*s.* net.—This part contains the following articles:—1. Studies on the Structure and Classification of the Digenetic Trematodes, by William Nicoll, M.A., D Sc., of the University of St. Andrews, with two plates. Many of these studies deal with new genera and species of this interesting group of parasitic worms. Amongst them are Stephanophiala laureata, found in the intestine of Salmo fari, and S. transmarina in the intestine of Salmo mykiss; Lebouria idonea, in the intestine of Anarrhichas lupus, and L obducta in the intestine of Bairdiella chrysura; Cainocreadium labracis in the intestine of Labrax lupus and Peracreadium genu in the intestine of Labrus bergylta; Fellodistomum agnotum in the gall-bladder and duodenum of Anarrhichas lupus; Steringophorus cluthensis in the intestine of Pleuronectes microcephalus; and Plagiorchis notabilis in the intestine of Anthus obscurus and Motacilla flava; each of these is more or less fully described. A table shows the chief comparative differences between the six genera of Allocreadiinæ. Two plates illustrate the text. 2. On the Anaspidaceæ, Living and Fossil, by Geoffrey Smith, Fellow of New College, Oxford, with two plates and 62 figures in the text. The Anaspidaceæ are shrimp-like animals found in freshwater pools in Tasmania and similar creatures have been obtained from the Permian—carboniferous measures. 3. On the So-called "Sexual" Method of Spore Formation in the Disporic Bacteria, by C. Clifford Dobell, Fellow of Trinity College, Cambridge. The author thinks that, in the disporic forms at least, no real sexual process occurs. 4. Studies on Polychæt Larvæ, by F. H. Gravely, M.Sc., junior demonstrator of zoology in the Victoria University of Manchester, with one plate and three text figures. 5. Some observations on Aciñetaria, by C. H. Martin, demonstrator in zoology at Glasgow University, with one plate and six text figures.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

DRIED EGG AND MILK PRODUCTS

(Casein, Limited, Sheepcote lane, Battersea, London, S.W.)

When food products are dried by such a process that on restoring water to them they appear again to be identical with the natural product they are obviously worthy of attention. A milk powder obtained by the ordinary method of evaporation by heat is no longer milk when water is added to it. The fat is separated amongst other things and the activity of the enzymes is destroyed in the process. The products of Casein, Limited, are, on the other hand, obtained by submitting a fine spray of the liquid to the action of a current of warm air. The result is that the liquid is instantly robbed of its water and a practically dry powder deposits. We found that the milk powder so obtained when treated with water yields practically natural milk again; there is no separation of constituents, the vital entities are not destroyed, and, moreover, the taste is indistinguishable from that of raw fresh milk. So with the egg powder which may be used for all practical purposes with the same success as the fresh egg. We have also examined a sweet whey powder and a powder consisting of the pure protein of milk. Laitproto, as the powdered casein is called, gave the following results on analysis: moisture, 7·80 per cent.; protein, 84·70 per cent.; and mineral matter, 7·50 per cent. The dry substance contains therefore about 92 per cent. of pure milk protein. The milk powder gave the following results on analysis, from which it will be seen that the original milk was of excellent quality and contained a full share of fat: moisture, 1·60 per cent.; mineral matter, 5·50 per cent.; protein, 22·05 per cent.; fat, 34·00 per cent.; and sugar, 36·85 per cent. The egg powder gave the following results: moisture, 4·30 per cent.; mineral matter, 3·70 per cent; protein, 54·00 per cent.; and fats, 38·00 per cent. We regard all these preparations with distinct favour; they are an obvious advance on food preparations dried by the agency of heat above coagulating point.

VIN DE VIE.

(Schweppes, Limited, 64, Hammersmith road, London, W.)

The use of grape juice as a beverage diluted with plain aërated water appears to be growing in favour, and as there is no reason for believing that such a beverage is not entirely wholesome the practice may therefore be commended. Dilute grape juice certainly affords a refreshing and palatable drink, and it appears to have a cooling effect which some ascribe to its acid constituents. Vin de Vie we find has been sterilised by a satisfactory process; it showed no signs of fermentation and therefore of alcohol in appreciable quantity. Search for preservatives was made without success. Our analysis gave the following results: alcohol, a trace; extractives, 16·95 per cent.; tartaric acid, 0·92 per cent; grape sugar, 15·15 per cent.; and mineral matter, 0·25 per cent. As is well known, grape sugar is the most digestible of sugars and, in fact, may be regarded as a predigested sugar which is fitted for direct absorption into the blood. Grape juice contains, however, other things besides sugar, amongst which are chiefly alkaline salts and a little protein. The juice is probably slightly laxative on this account, a property which has been remarked in the so-called "grape cure." A plentiful supply of grape juice has also been employed with favourable results in pulmonary as well as gastric and intestinal catarrh. It is also recorded that a regimen of grape juice reduces the albumin in albuminuria.

DRY YEAST TABLETS AND POWDER

(Matthaei and Co., 12 and 13, Cullum street, London, E.C.)

The use of yeast in therapeutics is well known, its effect probably depending upon its power to resolve complex bodies into simpler ones. Thus it has been used in cases where metabolism is obviously at fault, as in diabetes mellitus, some physicians assuming that it acts as though it possessed the ferment agents of the gastric and pancreatic juice. It has also been used in acne, eczema, and so forth. For these purposes it is desirable that the yeast should be clean and active, requirements to which we find these preparations comply. They are stated to be prepared from pure yeast by a special cold air process However that may be, we found both the powder and tablets active in their attack on sugar. Under the microscope it was easy to recognise a pure species.

"DE RESZKE" CIGARETTES

(J. Millhoff and Co., 17, Down street, Piccadilly, London, W.)

We are informed that these cigarettes have been prepared at the suggestion of the famous tenor whose name they bear. The result has been a blend of tobaccos which it is stated is free from irritating qualities even with delicate throats. According to our examination the tobacco in the one case appeared to be a carefully selected gain to that body. Mr. BLAND-SUTTON took the diploma of Fellow in 1884. He is surgeon to, and lecturer on surgery at, the Middlesex Hospital. He is well known as a most able surgeon and skilful operator. His contributions to pathology and to gynæcological surgery have been numerous and we think that he, too, would be an acquisition to the Council. There are, however, but three vacancies, and it must not be forgotten that Middlesex Hospital sends already two very able members to the Council Board in the persons of the President, Mr. HENRY MORRIS, and one of the Vice-Presidents, Mr. PEARCE GOULD. This amount of representation is, we think, as much as is justified by the size of the medical school of Middlesex Hospital. We do not doubt that Mr. BLAND-SUTTON will one day be a member of the Council of the College if he is not a successful candidate on this occasion.

Mr. W. H. H. JESSOP, like Mr. BLAND-SUTTON, became a Fellow of the College in 1884. He is senior ophthalmic surgeon to St. Bartholomew's Hospital, and we believe that he comes to the poll rather as an ophthalmic surgeon than as a hospital representative. There are considerable reasons why there should be an ophthalmic surgeon on the Council, and, in fact, for the past 30 years there has always been at least one seat occupied by a surgeon well acquainted with the surgery of the eye. At the present time Mr. RICHARDSON CROSS ably represents this branch of surgery, and although the vote of St. Bartholomew's Hospital can generally carry a candidate we are inclined to think that Mr. JESSOP's candidature on this occasion will not be successful, Mr. CRIPPS being also a candidate. But all the candidates are justified by their professional positions in expecting the support at the poll of the Fellows coming from their own schools, while some of them can rest their claims in a very distinct and notable manner upon a wider basis, so that the electors have a difficult task before them. Of the candidates seeking re-election Sir WATSON CHEYNE should be absolutely secure of success. Of the men who are coming forward for the first time Mr. BALLANCE's candidature appears to us to be the strongest. In the event of Mr. BALLANCE being elected to serve on the Council at the first time of asking, and looking upon Sir WATSON CHEYNE's seat as secure, there would only remain one seat to be allotted among three past councillors, Professor MAYO ROBSON, Mr. CLEMENT LUCAS, and Mr. HARRISON CRIPPS. The vote of St. Bartholomew's men will, then, probably serve to turn the scale between the three, but any one of them may be found above Mr. BALLANCE at the poll, past services rightly reckoning with the electorate.

◆

Non-Alcoholic Galenicals.

AS we pointed out in THE LANCET of May 29th, p. 1540, the new taxes which will be imposed on rectified spirit if Mr. LLOYD GEORGE'S Finance Bill be passed without amendment in this respect, will throw a grievous burden alike on hospitals and on those medical practitioners who supply medicines to their patients, or who have club practices. The present time may therefore be considered opportune for emphasising the possibility of reducing to a minimum the use of alcoholic preparations of drugs without loss of therapeutic efficiency or of what is known as pharmaceutical elegance. There is no room for doubt that many of the tinctures and other spirituous preparations of the British Pharmacopœia contain substantially more alcohol than is for any purpose necessary, and in nearly all cases the cost of a tincture depends far more on the solvent or menstruum than on the drug employed. Some tinctures are nothing but alcoholic solutions of definite substances—e.g., tincture of iodine, tincture of iron perchloride, and ammoniated tincture of quinine. The spirit in these three preparations can readily be dispensed with. Iodine is freely soluble in an aqueous, as well as in a spirituous, solution of potassium iodide; liquor ferri perchloridi of suitably modified strength may well replace its alcoholic equivalent; and even in ammoniated tincture of quinine the proportion of alcohol can be considerably reduced on the lines of the more agreeably flavoured ammoniated elixir of quinine of the British Pharmaceutical Codex. The majority of the Pharmacopœial tinctures are not, however, solutions of definite substances, but are dilute alcoholic extracts of various crude drugs. In many instances they contain much more alcohol than is necessary for the thorough extraction of the amount of drug which is ordered, and with respect to such no practical pharmacist would experience difficulty in preparing them in concentrated form for subsequent dilution with water. Examples of preparations of this type are the compound tinctures of camphor, cardamoms, gentian, and lavender. The use of the aqueous liquid extract of opium in place of laudanum has for many years been quite common. Tincture of cinchona, as is well known, precipitates on the addition of water, yet even in the case of this drug a glycerine preparation of equivalent alkaloidal strength is readily obtainable. The formula for this galenical is given by the British Pharmaceutical Codex as follows:—

Glycerinum Cinchonæ, B.P.C.

Liquid extract of cinchona	20 00
Tragacanth in powder	0 75
Alcohol	2 50
Distilled water	20 00
Glycerine sufficient to produce	100 00

This is a palatable preparation, much cheaper to produce than the tincture, and eminently suitable for use in a concentrated form. The group of preparations which includes spirit of chloroform and aromatic spirit of ammonia offers in some cases similar opportunities for economy. In St Thomas's Hospital much money has been saved by the adoption of an aqueous emulsion of chloroform—made with the aid of a small quantity of tincture of senega or tincture of quillaia—in place of spiritus chloroformi, B.P. So, again, by the use of oils which are free from terpenes a satisfactory "sal volatile" may be made with an extremely small proportion of alcohol. For many years some well-known manufacturing druggists have used glycerine as a preservative for liquid extract of cascara sagrada in place of the alcohol which the British Pharmacopœia prescribes for the purpose. The glycerine extract is more miscible, less nauseous, and in other respects wholly satisfactory. The list might be considerably extended, but enough has been stated to prove that so far as hospitals and private practitioners are concerned it is a simple matter to escape from at least some of the expense entailed by the increased taxes on spirits. Druggists who live in fear of the inspectors administering the Sale of Food and Drugs Acts are in less fortunate case. With respect to the galenicals which have been mentioned, it may be definitely stated that, given careful preparation, no difficulty need be anticipated as regards their keeping properties or their compatibility with other liquids. A tincture made with glycerine and water has, no doubt, a taste which to many is less attractive than its alcoholic equivalent. But this consideration is quite insignificant when it is remembered that equal therapeutic activity and equal convenience in handling may be secured at a great saving of expense by the avoidance of unnecessary alcohol in liquid preparations of drugs.

Social Betterment in America.

AMONG the many services rendered by ex-President ROOSEVELT to his country, few are likely to have a more abiding influence upon its welfare than the impetus which he has given to the cause of sanitary and social reform; a cause only second in its importance to the moral cleansing which he at least began to introduce into the conduct of mercantile and of municipal affairs. The District of Columbia, in which the city of Washington and the Presidential residence and offices are situate, is entirely independent of State legislation; and the city has been suffered to grow to its present magnitude in a somewhat haphazard manner, the effects of which were greatly aggravated after the civil war by the number of emancipated coloured people who sought refuge and a maintenance within its boundaries, and who were quite willing to disregard many of the ordinary requirements of decent and civilised life. In order to meet the wants of this class a number of flimsy tenements seem to have been erected upon ground originally intended to be reserved as the curtilages or gardens of better houses, and blind alleys of the same description were built up in the central spaces of what once were squares, with the general effect of crowding the city, even in the immediate neighbourhood of the best class of its habitations, with a series of slums and an aggregation of slum dwellers to which it would not be easy to find a parallel elsewhere. When Mr. ROOSEVELT became an official resident in Washington his attention was called to the various evils which had been suffered to come into existence there, and he appointed a Commission charged to inquire into the facts, and to recommend or apply such remedies as circumstances might permit. This Commission consists of 15 members, among whom there is a large medical element, and it resolved itself into special committees for the better conduct of the work entrusted to it. The reports of the Committee on Housing, of the Committee on the Building of Model Houses, of the Committee on Industrial and Personal Hygiene, and of the Committee on Social Betterment have just reached us, and we have only admiration for the spirit in which the various evils which these committees were appointed to encounter have been attacked, and for the good sense by which their acts and recommendations are characterised. The first three reports deal chiefly with matters which are occupying more or less the attention of all civilised communities, and to which, therefore, many parallels may be found elsewhere; but the report of the Committee on Social Betterment strikes us as being rather distinctively American in its character, and as dealing with subjects which elsewhere there has been too much tendency to ignore, or at least to regard as lying somewhat beyond the scope of public or official intervention. We would invite attention to some of its more distinctive features.

Perhaps one of the most characteristic of these is an elaborate inquiry into the amount of injury which is inflicted upon the community by the prevalence of the "*drug habit*," and, indirectly, by the activity of the makers and advertisers of the quack medicines by which this habit is largely created and fostered. It is said that during the last nine years 256 patients have been treated in the Columbia hospitals for the opium habit and 62 for the cocaine habit; while a large number of pharmacists report extensive sales of the alcoholic preparations of opium, such as McMunn's elixir, Squibb's mixture, and other proprietary or secret medicines containing opium. A list of no less than 38 largely advertised preparations, depending for their activity upon morphia, cocaine, or chloral, is furnished; and one at least of these, Mrs. Winslow's Soothing Syrup, which is said to owe its activity to morphia, is freely advertised in this country. We read also of extensively advertised "soft drinks" containing caffeine, extract of kola nut, and extract of coca leaf, "many of them sold at nearly every soda-water fountain or as carbonated goods without any warning to the public of the harmfulness of the ingredients which they contain." Another form of the same evil is the fact that a large number of "cures" for the drink habit or the opium habit are advertised by various charlatans, and that nearly all of them contain large quantities of morphia. Mr. SAMUEL ADAMS is quoted as having published a list of 16 advertised cures for the opium habit, all which contain morphia, and which have no other object than to substitute, for slavery to the drug obtained from the pharmacist, slavery to the same drug disguised, and purchased at a larger price from the "doctor," or "institute," or "society." "The Sunday newspapers and small weeklies teem with advertisements of drink cures, all of which are swindles." The report passes on to consider the effects of antipyrin and its analogues as advertised cures for headache, and of thyroid extract as a cure for obesity, saying, among other things, that 1665 cases of more or less serious poisoning, 54 of death, and 169 of "habitual use" were traced to the advertised headache remedies by a very moderate amount of inquiry. One of these "remedies," containing acetanilid and antipyrin, is advertised as Harper's "Curforheadake Brane Fude," an ingenious perversion of spelling which was declared by an American judge to be "misleading and therefore a violation of the law." Another important section of the report deals with the numerous proprietary medicines which are advertised in such terms as to suggest that they will produce abortion, another with the infanticide resulting from the systematic drugging of children, and others with "cures" for diphtheria, consumption, catarrh, cancer, rheumatism, epilepsy, and other forms of prevalent disease. Altogether, we learn that there were existing in the United States in 1900, [illegible] "patents" dependent opening was made in the perineum for drainage. The patient was placed in the lithotomy position and a full-sized median grooved staff was passed. On incising the perineum the finger entered a considerable cavity below the pubic arch to the right of the urethra, which was intact. A second tear in the bladder was then found, a large rent below and to the right of the neck. By inserting a large drainage-tube into this opening it was found possible to drain the bladder without interfering with the urethra. This was accordingly done and the operation was completed by passing a drainage-tube through the hypogastric incision into the upper tear and closing the remainder of the wound. The bones were approximated by pressure on the hips, the pelvis was strapped with a strip of plaster, and the knees were tightly tied together. No constitutional disturbance followed. The suprapubic tube was removed on the tenth day and the track slowly closed with a little suppuration. The perineal tube was left in for three weeks. A week after its withdrawal the patient micturated normally. A small urinary fistula persisted in the perineum for a few weeks, and healed completely in about three months. The patient made a complete recovery. Mr. Russell has not been able to discover any record of a similar accident, nor of any double rupture of the bladder, however produced. The escape of the urethra from injury was astonishing. A striking reflection is that the recovery from this severe injury was more complete and the ultimate loss sustained by the patient was much less than would have resulted from a relatively trifling blow on the perineum sufficient to damage the urethra.

GRINDERS' PNEUMOCONIOSIS IN SHEFFIELD.

THE dangers that result from dusty occupations have been long recognised, and among these the work of grinding edged tools holds an unenviable pre-eminence, probably owing to the irritating qualities of the particles of stone and steel which are here inhaled. We therefore welcome the inquiry which has recently been held by a Commissioner representing the Home Secretary into the question of the feasibility of laying down a scheme of regulations for the control of works in which the operation of grinding is carried on. The inquiry was held at Sheffield, the chief seat of the cutlery trade, and some striking evidence was given by Dr. Harold Scurfield, the energetic medical officer of health of the city, who has done much to call attention to the magnitude of the evil. He showed that the death-rate from phthisis is 15 per 1000 among grinders, whereas it is only 2·6 among males over 20 throughout the rest of the population; while the death-rate from other diseases of the respiratory organs is 5·6 per 1000 among these workers as compared with 2·1 among the general population. Among cutlers, whose work is less dangerous, the death-rate from phthisis is still 6 per 1000, and that from other respiratory diseases 7 per 1000. Two out of every three grinders die from consumption or other respiratory disease. Dr. Scurfield stated that he had paid a visit to Solingen in Germany, where similar work is done, and found that a great improvement in the health of the workers had resulted since a system of exhaust ventilation had been adopted, whereby the dust was removed as it was formed; and it is legitimate to hope that the same system may be inaugurated in this country. It is satisfactory to note that the employers through their representative at the inquiry evinced their willingness to coöperate heartily in any measures that might be found advisable. A curious point was brought out in the evidence given by Dr. E. L. Collis—namely, that the percentage of ill-health among the wet-grinders is slightly greater than that among the dry-grinders, although it might have been supposed that the laying of the dust by water would have prevented the occurrence of respiratory disease. It was suggested that here the evil resulted from the habit of tuberculous workmen of spitting into the trough in which the grindstone worked, and the consequent dissemination of the bacilli in the spray produced. This point appears to need further investigation. Throughout the inquiry it was impossible not to be struck by the difficulties introduced into the investigation by the application of the word "phthisis" to both tuberculous and simple fibroid disease of the lungs. It is most desirable that some word should be introduced to represent the latter condition, and as "pneumoconiosis" is too cumbrous for general use it might be suggested that "coniosis" or "coniasis" might be adopted, since it is on the lungs alone that the danger of dusty work falls and the prefix "pneumo" is not needed to distinguish this from other conioses.

MEDIÆVAL HOUSES AND PHTHISIS.

PULMONARY tuberculosis has been suggested by Mr. John Burns to be the result of social inequality, and this is true in the sense that those on the lower rungs of the social ladder, in addition to being badly fed and housed, inherit habits which make for the propagation of disease. The habit, almost universal amongst the poor in the remote Highlands of Scotland as well as in London slums, of keeping shut all windows and apertures through which the cold outer air may penetrate into their dwellings, is probably a relic of the time when the drenched serf or hunter crept back to his hut from the damps and fogs without, and, like an Eskimo, tried to forget the cold of the outer world in the lulling stuffiness—which was not necessarily warmth—of his domestic interior. The hut of primitive man was at first round, and as it passed through various stages of development to the square or oblong shape now universal, it never ceased to abound in dark nooks and sunless angles where disease germs, especially those of phthisis, might be harboured or bred. Before the days of glass, windows were at best small apertures. In his interesting "History of the House: the Struggle for Fresh Air and Light," Dr. Gould of Philadelphia expresses the opinion that "the habit of bad houses and of house diseases," following on a faulty method of building, "is the oldest of human habits." And in a series of admirable illustrations of primitive dwellings, from the round stone huts of the monks of Skillig and the oratory of St. Gallerus near Dingle, to "Teapot Hall" at Scrivelsby in Lincolnshire, he shows how unhygienically the early Celts and Saxons were housed. "Teapot Hall," which still stands, is probably a good specimen of an early mediæval dwelling. It is simply a slanting roof standing on the ground, and, as such, resembles the stone oratory of St. Gallerus. Old English serfs in the Middle Ages were perpetually drifting into towns, where they obtained freedom, but they doubtless brought their love of mere stuffiness with them, and as the early mediæval town was mainly built of wooden shanties it must have been designed much on the lines of "Teapot Hall." The roof-shaped cottage, as Dr. Gould shows, only gradually enlarged its proportions, and this it did by throwing out pent-houses, annexes, or oven-shaped constructions, which in their turn were quite elaborately roofed by a new system of rafters springing from the central roof-tree. A barn at Bolsterstone is shown in cross-section, most ingeniously, and at the same time inconveniently, enlarged by the addition of a kind of aisle. Air and light were the last things the old builders sought after. Indeed, they seemed, in countries north of the Alps, to aim at excluding both, even in buildings such as monasteries, colleges, or country-houses where some dignity was sought after. It is easy to conceive what an impetus such a bad theory and such bad buildings must in the Middle Ages have given to every form of dirt disease, but especially to pulmonary tuberculosis.

THE FESTIVAL DINNER OF THE HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

THE dinner in aid of the jubilee fund of the Hospital for the Paralysed and Epileptic was held on June 10th, by permission of the Lord Mayor of London, in the Mansion House. The Lord Mayor presided, and was supported by H.S.H. Prince Alexander of Teck, chairman of the board of stewards. Among those present were Lord Justice Kennedy, Sir William Gowers, Mr. Sheriff Baddeley, the Dean of Canterbury, Sir Felix Semon, Mr. Carl Meyer, and many members of the medical staff of the hospital. The chairman, in proposing the loyal toasts, mentioned that His Majesty the King had consented to visit the hospital on Nov. 4th to open the new buildings, and that the Princess of Wales had consented to visit the hospital in October to receive purses. The Lord Mayor then proposed "Success to the Jubilee Fund." In all some £50,000 were required for new buildings, especially for a new nurses' home He laid stress upon the excellent work which the hospital was doing and pointed out that medical men came from all over the world to attend the practice of the hospital. Mr. Frederick Macmillan, the treasurer, responded. Then came the toast of "The Medical Staff," proposed in an admirable speech by Mr. Comyns Carr, who reproached his hosts for putting him down to speak after dinner instead of before. Had the latter been the case he could have said to them what they had so often said to him, namely, "Avoid rich food, be sparing with your alcohol," but now what was the use of saying anything? Sir William Gowers responded. During the course of the evening subscriptions to the amount of £2719 were announced. The final toast was that of "The Chairman," proposed in a graceful little speech by Prince Alexander of Teck.

A FATAL CASE OF POISONING BY ATOXYL.

THE occurrence of toxic symptoms after the use of atoxyl has been observed and recorded in a considerable number of cases, the most serious being those affecting the eyes, such as retinal hæmorrhage, amaurosis, and optic atrophy. Koch observed 22 cases of blindness after its use in the treatment of 1633 cases of sleeping sickness. In addition to these ocular effects various symptoms have been frequently observed, including malaise, attacks of vertigo, insomnia, dryness and irritation in the throat, pains in the limbs, and various paræsthesiæ. In some cases slowness of the pulse and even anginal attacks have occurred, while anorexia, vomiting, diarrhœa, and jaundice indicate its effects on the digestive system. Albuminuria, nephritis, and painful micturition have also been described, as well as various cutaneous lesions. These toxic effects are analysed in a paper (published in the Munchener Medizinische Wochenschrift of May 11th) by Dr. Heinrich Schlecht, of Professor Strümpell's clinic at Breslau, and details are given of a case in which the administration of atoxyl was followed by death. The patient was a butcher, 28 years of age, who developed a chancre in November, 1907. Apart from an attack of enteric fever ten years before, he had always had good health. There was no history of epilepsy or of alcoholism. Ten weeks after the development of his chancre a maculo-papular rash appeared with condylomata at the anus. He was then treated by mercurial inunction for three weeks. A little later he was given five grammes of potassium iodide daily by the mouth and received four injections of 0·1 gramme of salicylate of mercury subcutaneously. After a further interval of six days, during which the patient felt well, atoxyl was given in four separate doses of 0·6 gramme spread over a period of eight days, the total quantity given being therefore 2·4 grammes The day after the last injection the patient became seriously ill with malaise, anorexia, vomiting, and sudden rise of temperature. Within a few hours epileptiform attacks supervened, with tonic and clonic spasms and complete loss of consciousness. The pupils were sometimes contracted, sometimes dilated, and insensitive to light. The tendon reflexes, which were at first abolished, later became exaggerated, and a Babinski reflex was obtained on both sides. A high degree of cyanosis supervened, respiration was sometimes deep, at others rapid and superficial, while during the fits breathing would cease for considerable periods, to be followed by markedly dyspnœic respiratory movements. The heart's action became very weak, the pulse rapid and small. The urine contained albumin and casts. Examination of the blood showed a marked leucocytosis and some polycythæmia. Death occurred in one of the epileptiform attacks. At the necropsy the heart muscle showed degenerative changes, and there was marked œdema of the lungs. The liver showed fatty and necrotic areas, and there were signs of marked destruction of red blood corpuscles both in the liver and spleen. The kidneys were large, soft, flabby, and congested. In the central nervous system the only changes observed were local proliferations of the neuroglia in the cortex and recent degenerative changes in the vessels. Dr. Schlecht inveighs strongly against the use of atoxyl for syphilis, blood diseases, and skin lesions for which ordinary methods of treatment are available. He suggests that there may be in some persons an idiosyncrasy to atoxyl, since toxic symptoms are on record after comparatively small doses, and he recommends the utmost care in its use. He gives no details of the source of the atoxyl used in the case he records. From the literature it would appear that some samples of atoxyl more often give rise to toxic symptoms than others, and it is possible that some impurity may be the cause of some of the serious effects observed. It is obviously of the utmost importance that the substance should be free from arsenates, and that it should contain its arsenic in the form of arsonate. Dr. Schlecht's case is a further indication that atoxyl is a drug which must be used with great discrimination, and that its effects must be very carefully watched.

A SERIOUS CASE OF MILK ADULTERATION.

THE North-Eastern Dairy Company, Limited, of Durham-road, Holloway, was recently fined £100, with £21 costs, at the North London Police-court for selling milk which contained 6 per cent. above the normal proportion of water. The conviction took place after the summons had been adjourned for further evidence, and on the second day a witness very damaging to the defendants was produced He was a man who had been in their employment and in that of their predecessors, a company entitled the Callow Park Dairy Company, for 25 years, and he deposed that on the day named in the summons he received and obeyed written instructions from the branch manager to put from four to six quarts of "separated milk" into churns containing pure milk. The circumstances which caused Mr. D'Eyncourt to impose the heavy fine mentioned were stated by him as follows: "At the first hearing the company had pleaded warranty of the milk to them by the farmer, and had put their servants into the witness-box to swear that it had not been tampered with by them. Consequently, if the man mentioned had not come forward and confessed, the case would probably have been dismissed, and the blame for the condition of the milk would have been cast upon the farmer who supplied it." In this connexion the learned magistrate observed pointedly that it was open to the Islington borough council to take further proceedings with regard to the witnesses whose evidence had been discredited. It may be added that four previous convictions for similar offences were proved and that the company was stated to have been fined on one occasion no less than £50 at the Thames police-court. In THE LANCET of June 12th will be found the text of the principal provisions of Mr. John Burns's Milk Bill directed against tuberculosis, from which it will be seen that the President of the Local Government Board proposes that all dairies (including dairy farms) shall be registered, and that Subsection 3 of Section 1 is as follows: "On the second or subsequent conviction of a dairyman of an offence against this Act or the orders made thereunder the court by which he is convicted may ...... order that the name of the offender be removed from the register of dairymen either absolutely or for such period as may be specified in the order." This subsection does not apply, and might usefully be made to do so, in cases outside the general scope of the Bill, which is directed against the sale of milk likely to be infected with disease. It is suggested, however, by the case of the North-Eastern Dairy Company, Limited, that unless care is exercised the limited company may lend itself to covering infringements of the new law relating to the sale of milk, so far as the penalty which consists in the removal of an offending dairyman's name from the register is concerned. Presumably, in the case of a company he will be a manager or servant for whom another can easily be substituted, and it may be suggested that the absence from the Bill of any direct recognition of the milk trade as conducted by companies may tend to weaken its practical application in the future.

TYPHOID CARRIERS.

THE important part played in the dissemination of enteric fever by persons who act as "carriers" of infection while themselves no longer suffering from the disease is now well established, as the Secretary of State for War recently explained in the House of Commons. A difficult problem is presented in the question as to how the danger thus arising is to be met. Any attempts made in this direction must be watched with the greatest interest. We have recently received a copy of a notice issued by Dr. D. S. Davies, medical officer of health of Bristol, which is aimed at this mark. It consists of two parts —one addressed to hospital physicians and others who have cases of enteric fever under their care, and the other to the convalescents themselves. Physicians are urged to keep a register of their patients and to endeavour to secure their periodical attendance for examination after they have been discharged from hospital. Patients who have suffered from the disease are warned of the danger which may still exist of disseminating infection and instructed to use special care and cleanliness in preparing food for others. The idea in both cases is excellent, but we cannot help fearing that difficulties will arise in carrying it out. In the first place, many patients will not wish for the trouble of reporting themselves at intervals, even during a period of six months as here recommended. Still less will they wish to bring up specimens of excreta for examination. Secondly, to make certain of finding the bacilli, if they are still present in the biliary passages, somewhat frequent examinations would seem necessary, as the organisms appear to be eliminated only at intervals in many cases. Thirdly, and this appears a point of special difficulty, what is to be done with a person who still harbours the bacilli? If he is not in any way ill himself he will certainly resent any attempt to immure him once more in hospital, and if such were insisted upon, patients would be very unlikely to present themselves for examination after discharge. Yet without such detention effective supervision and treatment would be difficult. Further, the means of disinfecting the biliary passages at present available are not, so far as we know, at all thoroughly ascertained, but in this connexion we refer our readers to an interesting paper by Dr. P. J. Cammidge on pancreatitis as a sequel of typhoid fever which will be found on p. 1739 of this issue of THE LANCET. It will on many grounds be especially interesting to note the results obtained in Bristol in dealing with this source of infection, and we can only hope that such success may attend the procedure as to encourage other localities to inaugurate a similar policy.

THE INCIDENCE OF PHTHISIS IN CALCUTTA.

WE have received a reprint of a paper[1] read by Dr. T. Frederick Pearse, health officer of Calcutta, before the Medical Section of the Asiatic Society of Bengal on the incidence of pulmonary tuberculosis in Calcutta. He alluded to the difficulty in obtaining statistics in regard to the general population for any part of India, except possibly Calcutta and the city of Bombay, since the recorded causes of deaths are merely those given by the friends and relatives at the burning ghats and burial grounds. The death-rates for pulmonary tuberculosis given by the Sanitary Commissioner with the Government of India are 0·17 per 1000 for the British army, 0·52 for the native army, and 3·21 in the jails. In Calcutta the officers of the Plague Department make inquiries into the deaths occurring in that city, and the mortality statistics of the city are corrected according to the information obtained. From a study of the figures since 1905, the year in which they were first available, Dr. Pearse finds that the death-rate from tuberculous disease averages 2·5 per 1000. A further analysis of the figures shows that the rate among males is only 2 per 1000, that for females being 3·5. Another interesting fact elicited is that the death-rate among Mahomedan females is 5·8 per 1000, as compared with 3 per 1000 among the Hindu women. These figures are much higher than those for England and Wales, where the general death-rate for the period 1901–05 was 1·9 per 1000. The high mortality among women in Calcutta is attributed to the conditions of life, notably to the deficiency of fresh air. Dr. Pearse's figures should serve to draw attention to this subject with a view of improving these conditions and lessening the mortality.

TUBERCULOUS MEAT.

WE have received a copy of a pamphlet on the subject of tuberculous meat published by the Public Health Department of the Corporation of London, with the object of rendering widely known, more especially to those concerned in the supply and sale of meat, the indications of tuberculosis both in the carcass and in the living animal. The Corporation of London has for many years past instituted legal proceedings against farmers, butchers, and other persons sending diseased or unwholesome meat into City markets, or for exposing it for sale. It appears that in many instances the offence is due to gross carelessness, but sometimes to ignorance of the symptoms and appearances of tuberculous disease. In order to supply the necessary information as to these matters, Dr. William Collingridge, the medical officer of health of the City of London, contributes to the pamphlet a description of the signs of tuberculosis in the carcass and organs. He describes in popular or butcher's language the appearances of tuberculous lesions in beef and pork, especially those in the glands and in the lungs, as well as those of pleural and peritoneal adhesions. He cautions butchers against the process of "stripping"—i.e., removal of "skin" from the inside of the ribs or flanks with the view of removing the signs of disease—and points out that the Local Government Board has ordered that "stripping" in the case of foreign dead meat shall be sufficient reason for condemnation. The symptoms in the living animals are detailed by Mr. James King, veterinary inspector to the Corporation of London; the symptoms of pulmonary disease are given and the characters of lesions of the udders are outlined. The owner of cattle which present the symptoms described is recommended to seek the advice of his veterinary surgeon. An extract from leaflet No. 100 issued by the Board of Agriculture and Fisheries (revised, May, 1907) is also given describing the characters of tuberculosis in pigs, giving warnings against feeding the animals on refuse milk and diseased offal from tuberculous cattle, and recommending improved sanitation and periodic disinfection of premises where pigs are kept. Some of the sections of this pamphlet are dated 1903, but it appears to have been re-issued with the addition to which reference has just been made. It is a very useful and instructive little document and one which cannot be too widely circulated amongst those for whom it is written. We gather that copies can be obtained on application to the town clerk at the public health department at the Guildhall.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE principal amounts received at the Mansion House or notified directly to us as having been collected on behalf of the Fund up to Tuesday evening last are a little below previous receipts; but the collections of smaller size show no abatement, and the total is about the same as it was last year at this date.

THE King has given to Mr. Arthur Andrew Morrison, M.D. Aberd., surgeon to the Deaconesses' Hospital at Alexandria, His Majesty's Royal licence and authority to accept and wear the Insignia of the Fourth Class of the Royal Order of the Crown, conferred upon him by the German Emperor.

THE Prince and Princess of Wales, as President and Lady President of the League of Mercy, have issued invitations to a garden party at Marlborough House on Wednesday, July 7th, at 4 o'clock.

Dr. William Stirling, Professor of Physiology in the University of Manchester, has been elected a foreign corresponding member of the Reale Accademia di Medicina of Turin.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS

(Continued from p 1711)

LAST week we described the very practical exhibition which under the auspices of the National Association for the Prevention of Consumption and other Forms of Tuberculosis has been held during the past fortnight at the Art Gallery, Whitechapel. It remains to give some account of the conference and lectures which have been given in connexion with the exhibition.

The public has, we believe, now realised the necessity for combating the terrible scourge which, it is calculated, exacts a death-toll from the world of 5,000,000 every year; for, to put it in Mr. Burns's striking way when he opened the exhibition on June 2nd, "a London perishes *annually from one disease, tuberculosis.*" We in this country, where the figures are steadily and greatly improving, lose a population equal to that of York London alone has 9176 deaths from tuberculosis, which means that more people die from consumption during any one year than officers and men were killed in the South African war. One of the most satisfactory parts of Mr. Burns's opening speech was the statement that he was there on behalf of the Prime Minister especially to identify him and the Government with the National Association in the good work which it was undertaking. His own department, he said, was doing its portion of the public work. It had issued a monumental report by Dr. H. T. Bulstrode, and what that report had not done he thought the book of his present chief medical officer, Dr. A. Newsholme, had secured. The Food Protection Regulations Act had done a great deal to stop unsound meat coming into this country, and he believed that by a more rigid administration of that Act and the Sale of Food and Drugs Act, through the agency of local authorities, much good would be done. He hoped that before this session ended the Housing Bill would be on the Statute Book, and he was glad to say that the Milk Bill had been more favourably received than he had hoped for. He trusted soon to follow up the Notification of Tuberculosis Order by a circular to Poor-law authorities on the conditions under which Poor-law relief should be given to outdoor consumptive paupers.

The Annual Meeting.

The tenth annual meeting was held on June 4th and was presided over by Lord BALFOUR OF BURLEIGH, the chairman of the council of the association, among those present being Sir Constantine Holman, Dr. Theodore Williams, Dr. A. Ransome, *Dr. R. W. Philip, and Miss Broadbent. In moving* the adoption of the report the Chairman said that there was no subject more important to the well-being of the nation than the prevention of the ravages of consumption in all its forms. Public attention had at last been arrested and directed to the question, and the association had chosen an appropriate time to hold its exhibition. People were beginning to recognise that there were methods not difficult of adoption by which all forms of pulmonary disease might be successfully combated and many lives saved to the State. Nothing was more remarkable than the awakening of all our Government departments during the past few months in connexion with the subject. The exhibition, he said, brought directly to the attention of those who were principally concerned, in the most conspicuous and helpful manner, the things of which they should take note, and it was a most hopeful fact that on the opening day 5000 people had passed the turnstiles. In no department of medical science had greater strides been made than in the prevention and cure of tuberculosis. The only matter for regret in the council's report was the statement that the publication of its journal had been stopped owing to financial reasons. There was, he said, no institution which did a greater work for the well-being of the population than the National Association for the Prevention of Consumption, and he appealed earnestly to everyone who was interested in the subject to strengthen the hands of the association.

Dr. THEODORE WILLIAMS, vice chairman of the council, who seconded the motion, said that a very satisfactory reduction of consumption had been effected in this country of late years, the death-rate having been reduced to rather less than one-half of what it had been. To abolish the disease from the land might not be possible, as it would imply the abolition of poverty and misery of all sorts and the settlement of the housing question, but he had no doubt that a still further reduction would take place in the future.

In our report of the exhibition we drew attention to some of the more popular exhibits, and said that they had a more potent effect upon the minds of the really poor or ignorant than the scientific part of the exhibition. We are glad, therefore, to know that some of the members of the National Association share our convictions. Dr. R. W. PHILIP, in moving the addition of names to the *list* c [illegible] members of the council, incidentally [illegible] more space should be d [illegible] he question, even at the [illegible] stical aspects. The names of Mr. D. Shackleton, M.P., Dr. Arthur Ransome, Sir J. W. Moore, Professor G. Sims Woodhead, Dr. J. C. Thresh, Dr. Jane Walker, Dr. H. W. McConnel, and Miss McGaw were added to the list of members of the council, and those of Dr. Dawson Williams, Sir Alexander Kinloch, Sir John McFadyean, Dr. Arthur Newsholme (medical officer to the Local Government Board), Mr. J. Patten McDougall (Registrar-General for Scotland), Mr. T. J. Stafford (medical commissioner to the Irish Local Government Board), Dr. J. Niven (medical officer of health of the city of Manchester), Dr. E. W. Hope (medical officer of health of the city of Liverpool), and Professor S. Delépine (professor of pathology in the Victoria University) to the list of vice-presidents.

The Conference.

At the conference, which was held from June 8th to 10th, the subjects of discussion fell under the heads of (1) the Detection of Consumption, (2) the Treatment of Consumption, and (3) the Prevention of Consumption. It was attended by a large number of delegates from public health authorities throughout the kingdom. On June 8th Sir T. Clifford Allbutt, Regius professor of medicine in the University of Cambridge, presided. In opening the discussion, he said that his long professional life extended back to a time when neither a knowledge of the nature of the disease nor an efficient practice of its therapeutics really existed. Scientific knowledge of the treatment of phthisis dated from 1882, when Koch discovered the bacillus of tuberculosis. Referring to the treatment of the disease, he pointed out the need of some degree of segregation for advanced and incurable cases in order that infection might not be spread. Milk, which was an important factor in the transmission of the disease, should be under rigorous supervision as regarded supply and transmission. At the same time he warned his hearers that if costly provisions were too quickly forced upon farmers and dairymen any good purpose would be defeated.

Dr. H. Scurfield, medical officer of health of Sheffield, read a paper on the Compulsory Notification of Tuberculosis and its Value. In it he described the procedure which had been adopted at Sheffield. For the examination of sputum arrangements were made by the corporation with the bacteriological department of the University of Sheffield. On the first visit of an inspector to a house where a case was notified, a history of the case was obtained and a paper detailing advice was given to the sufferer. The poorer classes were supplied with pocket spittoons. The case was revisited at regular intervals and where found necessary the apartment or apartments were disinfected. Hospital accommodation was provided for both male and female patients. This served three purposes: (1) it educated the patients; (2) it gave the relatives a rest and an opportunity of thoroughly disinfecting the home; and (3) it enabled suitable cases to be selected for sanatorium treatment. Treatment on sanatorium lines was also given in the Sheflied Royal Infirmary and in the workhouse hospitals. He found no opposition to notification. One point upon which he laid great stress was that patients should be taught to clean their own spittoons and generally to help themselves, as in many sanatoriums everything was done for patients, with the consequence that when they left these institutions and returned home they were quite helpless.

On the same day Dr. Philip read a paper on the Dispensary System, and Miss Cummins, lady almoner at St. Thomas's Hospital, a paper on Consumption and Hospital Out-patient Departments.

On June 9th Dr. Arthur Latham, physician to St. George's Hospital, opened a discussion on the Sanatorium. He pointed out that more coördination was needed in the organisation of sanatorium treatment, and he thought it would be better to build sanatoriums for large numbers of people rather than to have a great number of small institutions scattered up and down the country. He commended the insurance system adopted by post-office employees and hoped the scheme would be extended to industrial concerns.

Dr. M. S. Paterson (Frimley Sanatorium) said that the real test for the sanatorium treatment of a patient was his general condition. It was a mistake to think that early cases were necessarily the most suitable for sanatorium treatment. A man with extensive disease who had been able to maintain himself for two years and still remain in good condition had a better right to treatment in a sanatorium than one in an earlier stage of better physique with no stamina. Dealing with the subject of graduated work for patients, he said that great care was necessary in the selection of patients. In the system adopted at Frimley a commencement was made by walking exercises of gradually increasing distances, basket carrying followed, and later the use of tools of gradually increasing weight. The tests for the higher grades of work were a satisfactory temperature, good appetite, and a general sense of feeling well. Physical improvement had a psychological effect; sullen and apathetic persons became transformed into lively and cheerful individuals. It was most important that the work should have a definite object, as patients hated nothing as much as work which was of no practical utility. Patients with a temperature of 99° F. and a headache required absolute rest. If while working the temperature rose to 99° or over, the patients should be put to bed. Those on light work often did not improve rapidly because the work was not hard enough to bring about its good result; with slightly harder work improvement followed in many cases.

Dr. Jane Walker, medical superintendent of the East Anglian and Maltings Farm Sanatorium, Nayland, described the work done in the institution. In her experience the rest treatment in sanatoriums was demoralising and she insisted on work for both sexes. At Nayland, in addition to domestic tasks the work consisted of lace-making and gardening.

Dr. H. W. McConnell (Matlaske Hall, Norwich) contributed a paper on the After-Care of Sanatorium Patients.

The Lord Mayor of London, who presided on June 10th, introduced further discussion by saying that nothing had conduced to the increase of consumption more than ignorance.

Dr. Duncan Forbes, medical officer of health of Brighton, read a paper on the Sanatorium as an Educational Agency.

Dr. E. W. Hope, medical officer of health of Liverpool, discussed the right connexion of the municipality with the prevention of consumption. He showed how by improving the housing conditions in the city of Liverpool tuberculosis had been successfully combated. Quoting the report of a special commission of inquiry which was held 60 years ago into the health of the great towns of England, he said that from a sanitary point of view Liverpool was then behind all other towns. From that time onward Liverpool had been the seat of war against tuberculosis. The report referred to showed that 100,000 persons in Liverpool were living in houses totally unfit for human habitation, 40,000 living in cellars. Nothing could be more useful or instructive than the study of the difficulties encountered in remedying this state of things, from which it would be seen that the gradually increasing diminution of the evils was accompanied by coincidental decline of tuberculosis. Some 2000 dwellings had been erected in Liverpool upon sites of areas on which insanitary dwellings had been destroyed, and these dwellings had been reserved only for the people dispossessed. In 1907–08 the phthisis mortality rate in the corporation buildings was 1·35 per 1000, actually lower than that of the city taken as a whole. Besides those houses designed for the very poor, 1400 well-constructed four-roomed cottages under £12 a year rental had been erected in the last seven years by private enterprise on the outside of the city, and 5000 houses at a rental of between £12 and £18. In all these houses the amount of phthisis was extremely small. Since 1864 the number of insanitary houses demolished by the corporation was approximately 8000, at a total cost, including schemes in hand, of £919,084. The work of the Liverpool corporation in this matter necessitated a large staff for the purpose of enforcing regulations, but breaches of the law had become less and less frequent, and it was quite clear that time, patience, and knowledge could satisfactorily improve the most insanitary conditions.

Dr. J. D. Stanley (Birmingham) gave an interesting description of the municipal sanatorium belonging to the Birmingham corporation which had been built on the Cotswold Hills.

Dr. J. E. Squire, C.B., speaking with regard to tuberculosis in schools, said that infection could be rarely traced to the school. The real cause was the home, and school authorities should have some power in controlling infection from that source. Parents ought to recognise their responsibility and give something in return for free education. Something in this way they could do by looking after their children better.

On the afternoon of June 10th there was a demonstration of Meat Inspection by Mr. J. King, chief veterinary inspector at the Metropolitan Cattle Market, and during the period that the exhibition has remained open popular evening lectures have been given by Professor Sims Woodhead, Dr. Hector Mackenzie, Dr. Theodore Williams, Dr. Frederick Rose, Dr. Newsholme, Dr. Nathan Raw, Mr. P. M. Short, and Mr. C. Garland.

Up to the time of going to press more than 50,000 persons have passed the turnstiles.

SANITATION IN INDIA.

VII.[1]—LUNATIC ASYLUMS.

Bengal.

Colonel R. Macrae, I.M.S., the Inspector-General of Civil [illegible] the lunatic [illegible] atics in the [illegible] n Dec. 31st the number was [illegible]. The admissions numbered for the year 181, or seven less than in 1906. The numbers discharged were 104, against 136 in 1906. This decrease in the number of the discharged is attributable to the survival of a large number of chronic cases at the Berhampore asylum who will never be fit for discharge. The total number discharged cured fell off mainly for this reason from 89 in 1906 to 69 in 1907, the percentage of recoveries on daily average strength being 10·76 and 8·12 respectively. However, the result compares favourably with the rate of recovery in English asylums, which, after excluding the statistics of the idiot establishments, was 8·31. With respect to the sickness and mortality, the total number of hospital admissions fell from 850 in 1906 to 555 in 1907, the largest reduction taking place at Berhampore, many sanitary [illegible] rried out at the asylum during t[illegible] has been remodelled, whilst at [illegible] ector-General closed-in verandah [illegible] ıp and doors removed, [illegible] ments resulted in the better state of general health was shown by the fact that the female inmates did not share in this improved health, but, be it remarked, the portion of the old asylum which they occupy was not readily susceptible of much improvement. At Patna the admissions rose from 119 in 1906 to 152 in 1907. Bowel complaints were more than twice as common in 1907 than in 1906. The Inspector-General during his annual inspection, however, noticed defects in the drinking water. These have since been remedied, and in consequence the superintendent reports a noticeable reduction in this class of disease. At Berhampore the bowel complaints showed a decided falling off, the admissions being 31, against 101 in 1906. This was due to the improvements mentioned above, and also to the fact that the patients were regularly examined and treated for intestinal parasites. Tuberculous phthisis as usual accounted for a large number of admissions. Lunatics all the world over are, however, extremely liable to phthisis. Fever was less common, there having been 185 cases, against 267 in 1906, this favourable result being probably due to the prophylactic issue of quinine during the unhealthy months. The total deaths on daily average strength was 8·94 per cent., against 10·27 in 1906, and 9·19 in 1905. This death-rate was lower than that of the asylums in Eastern Bengal and Assam, United Provinces, the Punjab, and Madras, and was even less than that recorded in 1906 in the county and borough asylums in England (10·11).

With reference to the form of lunacy with which the asylums had to deal, mania was the most frequent, furnishing 54·08 per cent. of the cases. Melancholia accounted for 20·92 per cent. Other forms were those of general paralysis of the insane (one case), mental stupor (two cases), and delusional insanity (three cases). Physical causes accounted for 41·84 per cent. and moral causes for 12·24 per cent. of the admissions, whilst the cause was not known in 45·92 per cent. of the cases. 21 cases were attributed to *ganja*. The manufacturing department of the jails of the province was engaged in road-making, carpentering, and basket-making. The Inspector-General last year suggested the discontinuance of labour in connexion with mustard oil pressing at Berhampore; the superintendent of the jail reports that this suggestion, where carried out, has been decidedly beneficial to the patients who are employed instead on other more suitable and genial occupations. At present schemes for a central lunatic asylum for natives and of another for Europeans at Ranchi are under consideration; both these asylums have been planned on the villa colony system, and if carried out as designed will be superior to any similar institution ever built in Asia. Finally, the Inspector-General acknowledges fully the efforts made by the superintendents to render the lives of the lunatics contented, comfortable, and happy. It must be a pleasure to work under so efficient an Inspector-General as Colonel Macrae, who has succeeded in rendering a most interesting report on a subject that does not lend itself naturally to exciting interest in the average reader. This excellent report concludes with the usual appendices.

Eastern Bengal and Assam.

The statistical returns of the lunatic asylums for this province for 1907 are furnished by Colonel David Wilkie, I.M.S., the Inspector-General of Civil Hospitals, Eastern Bengal and Assam. There are two asylums in the province—namely, one at Dacca, the other at Tezpar. The number of inmates remaining in both asylums on Jan. 1st, 1907, was 472, against 425 in 1906. During the year 104 lunatics were admitted, against 147 in 1906; but though the number of admissions was less, the total population treated was slightly greater, being 576 against 572, whilst the daily average number rose from 454·68 to 475·91. This is explained by the fact that the number under detention at the commencement of the year was larger than in 1906. The number discharged was 55, including three escapes from the Tezpar asylum, as against 72 with three escapes in 1906. Of these, 36, or 7·56, were "cured," 13 were "improved," and three "unimproved" made over to their friends.

As in former years, mania was the chief form of insanity, 73·08 of the admissions being classified under this head; melancholia accounted for 15·38 per cent. Of the total 104 admissions, the causes of insanity were known in only 43 cases, or 41·34 per cent.; in 30 of these 43 cases the cause was physical, and in the remaining 13 it was moral. Amongst the specific causes, *ganja* smoking was by far the most frequent.

Central Provinces.

Colonel P. A. Weir, I.M.S., the Inspector-General of Civil Hospitals, Central Provinces, furnishes this report. As regards the number of lunatics for the year 1907, we find the aggregate total admission in 1907 at Nagpore asylum was 85, of which 34 were males and 51 females. At the Jubbulpore asylum 15 males and one female were admitted. The daily average strength was 317·15, against 298·53 in 1906, the increase of 19 being mostly made up of females who numbered 14 to 5 males. With respect to the disposition of the two sexes, the necessary accommodation being at last completed on July 1st, 1907, all the insane females at Jubbulpore, 36 in number, together with their attendants, were transferred to the Nagpore asylum, and the female side at Jubbulpore thus became available for receiving males. There was slight overcrowding on the male side at Jubbulpore until the transfer of the females. It had since been decided to transfer all the Jubbulpore males to Nagpore so as to give up the former asylum entirely; this, it was hoped, would be possible by October or November of 1908. The provision of the necessary additional accommodation for patients and staff is being proceeded with.

There were 28 cures, 14 at each asylum, against 17 in 1906, and three were discharged improved. The deaths were 26 against 31 in 1906, the chief causes being epilepsy. With respect to the form of insanity exhibited, mania as usual headed the list, amounting to about 75 per cent., melancholia causing 5 per cent., dementia 11 per cent., idiocy 8 per cent., and other forms 1 per cent. C[illegible] or improved as much as 87 per [illegible] With regard to the causation [illegible] causes were assigned; of these, 28 per cent. were attributed to the use of *ganja* and 10 per cent. to that of alcohol.

United Provinces of Agra and Oudh.

The report of the asylums of the United Provinces of Agra and Oudh for 1907 is furnished by Colonel R. D. Murray, I.M.S., Inspector-General of Civil Hospitals, United Provinces. This report shows that the total admissions fell from 328 in 1906 to 273 in 1907, and the total population from 1537 to 1481. There was also a decrease in the daily average strength. The number of cures increased from 124 to 146, the number of deaths fell from 130 to 110, and the daily average sick increased from 90·18 to 99·83. There was a slight increase in the percentage of cures to the daily average strength, but the percentage of cures to admissions rose from 13·33 to 20·67. The percentage of deaths to the daily average strength fell from 10·69 to 9·13. The death-rate in the English asylums during 1906 was 9·85 per cent. on the daily average number resident, so that the asylums of these provinces compare very favourably indeed with those of England.

---

[1] Nos. I., II., III., IV., V., and VI. were published in THE LANCET of April 10th (p. 1067) and 24th (p. 1199), May 1st (p. 1269), 15th (p. 1412), and 22nd (p. 1480), and June 5th (p. 1630), respectively.

As regards deaths, the high death-rate of Agra for 1906 of 85 has been reduced in 1907 to that of 49. This number would have still further been reduced to 30 if influenza, which was very prevalent in Agra, had not unfortunately broken out in the asylum in November. The 19 deaths from influenza out of the 62 admitted to hospital occurred during the last six weeks of the year, and were immediately due to the extremely rapid onset of pneumonia. It was treated throughout as an acute infection, and was confined to that section of the asylum where the first case appeared. Amongst the facts noted with regard to this epidemic was the experience that in many cases where the patients survived over the third day symptoms of enteritis supervened. The influenza death-rate was 30 per cent., but, as the Inspector-General points out, it must be remembered with reference to this that the patients were suffering from insanity, which reduces the power of resistance to the disease to the lowest. Of the remaining 30 deaths dysentery accounted for ten. There was only one death from heat-stroke, against 18 in 1906. A great improvement in the health returns of the Benares Asylum has been effected by the reintroduction of the dry earth system of conservancy for the flushing system; the latter was stopped in June, 1907. During the flushing system the health of the asylum remained as bad as it had been since the system was introduced, and 21 deaths occurred during the first six months of the year. With the introduction of the dry earth system the health of the asylum has gone back to its former excellent standard, and though 14 deaths occurred during the second half of the year, some of them contracted their ailments during the first six months, whilst no fewer than six were from causes which were non-preventable. There is now every reason to hope that the asylum has reverted to its former healthy condition. Colonel Murray has furnished an excellent report.

EGYPT IN 1908.

(Concluded from p. 1632.)

Sir Eldon Gorst's report on Egypt in 1908 is so succinctly expressed that compression within the limits of an ordinary review is a task of no small difficulty. In some places the only way to do justice to the author would be by wholesale transcription. All the subjects dealt with are not, of course, topics for discussion in a medical journal, but if all that are unsuitable were to be eliminated in the present case there would nevertheless remain such a mass of suitable topics that adequate notice of many of them would have to be foregone. To continue our detailed notice:—

Hashish.—It is notorious that the employment of Indian hemp as a narcotic and stimulant has long been widespread throughout Egypt, but until lately the efforts of the authorities to prevent or restrict the practice have been perfunctory. The subordinate officials charged with the execution of the repressive measures being for the most part consumers of the drug themselves were by no means zealous in carrying out the more or less half-hearted orders they received. Of recent years, however, a great improvement has taken place in this respect. Hashish is not produced in the country, the supply being introduced entirely by smugglers, and serious attempts to check the introduction are now made at the various custom houses as well as by the coastguard. Sir Eldon Gorst does not state the quantity of hashish that was seized and confiscated in 1908, but in 1907 it amounted to 16,290 kilogrammes, or about 320 cwt., while the previous year the total was 15,380 kilogrammes. The daily dose consumed by a *hashash*, or person addicted to the drug, being comparatively infinitesimal, an idea can be formed of the number of consumers as well as of the magnitude of the trade which can support such drains on its resources. During the three years ending 1908 no fewer than 6095 establishments where hashish could be procured were permanently closed by order of the tribunals, 273 of these dens being the property of Europeans. The proportion of hashish patients to the total number admitted to the lunatic asylum was 8 per cent. in 1908, whereas during the preceding triennium the yearly average was 14 per cent. As Sir Eldon Gorst observes: "This is a remarkable reduction and may be regarded as encouraging, although too much stress must not be laid on the figures for a single year. It would appear to show that an efficient coastguard service, which is to-day almost entirely occupied in preventing the smuggling of hashish, coupled with the adoption of strict police measures in the towns, has succeeded in limiting very materially the facilities for indulging in this lamentable habit." The reduction of hashish lunacy is no doubt a matter for congratulation, but on the other hand the unwonted consumption by the native Egyptian of spirituous liquors affords food for reflection. Formerly the *fellah* was the most temperate of mortals, but unhappily this excellent characteristic is no longer deserved. The drinking habit is in process of formation in Egypt. In the year 1908 hashish caused 36 admissions to the lunatic asylum, but there were 35 due to the abuse of alcohol.

Plague and cholera.—In a short section Sir Eldon Gorst mentions the occurrence of 1511 cases of plague distributed over 142 centres of infection. In 1907 there were 1253 cases in 107 centres. It is now nine years since the present infection of the country occurred, and until 1906 it was practically confined to the Delta and Middle Egypt, where the disease was almost invariably of the bubonic form. When, however, Upper Egypt was invaded it assumed the very infectious and fatal pneumonic form. The concealment of cases is still very prevalent amongst all classes of the population. With reference to this unfortunate tendency Sir Eldon Gorst observes: "In this, as in other epidemics, the success or failure of the measures prescribed by the Government must very largely depend upon this important question of obtaining early information, and it is in overcoming ignorance and prejudice in this respect that the most difficult task of the officers of the Sanitary Department consists." Although cholera was very prevalent last year in the Hedjaz, and subsequently a few cases occurred in the quarantine camp at Tor, no invasion of Egypt took place. The disease was still present in Southern Russia when Sir Eldon Gorst was writing his report, but so far "the pilgrim season had shown no signs of cholera infection."

Village barbers.—One of the most urgent needs for Egypt is the provision of efficient medical aid for the great mass of the population. The medical officers of the Sanitary Department do what they can, but their number is altogether inadequate. The village barber is still the universal refuge in sickness, and it is not too much to say that his ministrations are worse than useless. On this head Sir Eldon Gorst's remarks are so clear and to the point that no condensation of them is possible.

> The office of village barber is an institution of great antiquity in Egypt. Without going into this functionary's history it may be said that his duties consist principally in performing vaccination and various [illegible] births and deaths, and furnish- [illegible] rities. He obtains no remunera- [illegible] small fees from his clients, and his interests are closely bound up with the goodwill of the village Omdeh. The functions and responsibilities which he exercises have not contributed to independence of character or to a sense of duty to the superior authority which appoints but does not pay him. The rank and file of this class are consequently of indifferent quality, and really trustworthy men are few and far between. Last year the experiment was made of utilising the village barbers in connexion with the special measures for dealing with pneumonic plague in Upper Egypt, and a small sum was devoted to paying a few selected barbers in each province, in order to obtain more speedy and trustworthy information than would be furnished by the villagers, and [illegible] suspicious deaths or illness in the [illegible] In most cases the offer of a small [illegible] n all that was required. Reports from the provincial authorities are unanimous in testifying to the advantage of the system, and in recommending its further extension on a permanent basis. It must be admitted, however, that, apart from financial considerations, the general mass of the barbers are not as yet worthy to be taken [illegible] The majority are illiterate, many are [illegible] of indifferent character have bec [illegible] ore desirable candidates.

The second part of Sir Eldon Gorst's report is concerned with the Soudan and is drawn up on the same lines as the first. Under the heading, "Public Health," the writer states that the country has been free from any serious epidemic of infectious disease during the past year, but Dr. J. B. Christopherson reports minor outbreaks of cerebro-spinal meningitis, infectious pneumonia, small-pox, chicken-pox, diphtheria, and dengue, and there have also been isolated cases of kala azar, Malta fever, and blackwater fever. At least five cases of kala azar have been treated in the Khartoum hospitals, and Sir Eldon Gorst much regrets to record the death of Captain Craik, after being invalided to England, a victim to this malady, for which, he adds, no cure has yet been discovered. A medical officer is being sent to study the disease in Kassala where most of the cases have originated. The number of out-patients treated during the year has increased from 94,051 in 1907 to 121,214, that of in-patients remaining at a little over 7000. The arrangement whereby quinine can be procured at post-offices is evidently appreciated by the public, 6350 boxes having been sold in 1908. The new hospitals at Port Soudan and Atbara are practically completed and the new Khartoum hospital should be ready for occupation during the present year. Dr. Christopherson considers that attempts to train native women in nursing have so far proved a failure and that Arab and Soudanese boys make better hospital attendants. In conclusion, Sir Eldon Gorst states that Captain H Ensor, R.A.M.C., has submitted a final and invaluable report to the Soudan Sleeping Sickness Commission, the result of his investigations in the Southern Bahr-el-Ghazal. Captain Anderson, R.A.M.C., who has now succeeded him, will meet Sir David Bruce at Gondokoro in order to confer with him upon the general situation.

We regret to say that Sir Eldon Gorst largely ignores the prevention of disease in his report. He notices most subjects and dwells at great length upon some of them, notably the law and education, but his observations under the heading of public health are not only exceedingly brief, but refer exclusively to the cure of maladies already contracted, and make no reference whatever to the adoption or otherwise of sanitary measures properly so called. It is true that the drainage of Cairo is mentioned, and there is also some allusion to overcrowding and an improved water-supply, but these highly important matters are only lightly touched, and it seems doubtful whether their connexion with prolonged life and a lower death-rate is thoroughly appreciated. No doubt much good sanitary work was done during the year, but we are not told so. That a great deal remains undone is evident from the letters of our Sanitary Commissioner. In Egypt the infant mortality is appalling. We should be glad to learn what has been done towards diminishing it. Are medical officers of health appointed in sufficient numbers, and have they been given power to enforce the requirements of elementary hygiene? Has anything been done to ameliorate the condition of the innumerable *birkets*, which serve alike as dumping-ground for filth of every description and as reservoirs for drinking water? It would be easy to multiply such questions, but the foregoing will suffice. It is high time that persons in authority should learn that nothing on earth is so insanitary as disease, and that the primary object of every true sanitarian is its extinction. Incidentally it is well to cure disease, but the real business of a medical man is to prevent disease occurring. It is better to prevent one case than to cure ten. Not many years ago Egypt was looked upon with suspicion as a place of residence. Insurance companies used to charge extra premiums for permission to reside there. Have the conditions that make for a healthy life improved since the British occupation? Apparently they have to judge by the yearly increasing crowds of visitors; but, on the other hand, the state recorded by our Sanitary Commissioner is, to say the least, unsatisfactory.

THE INDIAN MEDICAL SERVICE: ANNUAL DINNER.

THE annual dinner of the Indian Medical Service was held at the Gaiety Restaurant, London, on June 10th, the chairman being Surgeon-General G. Hay, in the absence of Sir George Birdwood, K.C.I.E., through ill-health. The guests invited were General Sir O'Moore Creagh, V.C., K.C.B., the Commander-in-Chief in India elect; Sir William Church, President of the Royal Society of Medicine; Mr. Henry Morris, President of the Royal College of Surgeons of England; Mr. Austin Low; Dr. Squire Sprigge, the Editor of THE LANCET; and Dr. Dawson Williams, the Editor of the *British Medical Journal*. The following officers were present:—

Surgeon-Generals.—P. H. Benson, A. M. Branfort, C.I.E., W. R. Browne, C.I.E., J. Cleghorn, C.S.I., J. P. Greaney, L. D. Spencer, P. W. Sutherland, and B. Williamson.

Colonels.—W. E. Cates, D. E. Hughes, C. H. Joubert de la Ferté, H. G. L. Wortabet, and W. A. S. Wynne.

Lieutenant-Colonels.—W. G. Alpin, N. L. Bartholomeusz, A. T. Bown, W. J. Buchanan, Sir R. H. Charles, K.C.V.O., A. Duncan, G. A. Emerson, P. J. Freyer, G. H. D. Gimlette, H. Herbert, R. A. K. Holmes, E. R. Johnson, D. F. Keegan, S. Little, C. C. Manifold, R. J. Marks, C. Monk, J. Moorhead, J. O'Brien, A. Stephens, T. W. Stewart, A. W. F. Street, C. M. Thompson, W. H. Thornhill, D. Warliker, G. Waters, A. H. Williams, and F. W. Wright.

Majors.—H. Bamfield, A. E. Berry, J. F. Blood, C. Bowle-Evans, W. S. Caldwell, C. F. Fearnside, J. Fisher, P. C. Gabbett, G. G. Giffard, C. H. James, A. J. Macnab, W. Selby, D.S.O., G. B. Smith, F. W. Watling, C. G. Webster, and E. H. Wright.

Captains.—W. R. Battye, F. F. Elwes, G. King, J. T. Leary, R. A. Lloyd, J. L. Lunham, J. H. Murray, W. S. Patton, A. E. H. Pinch, M. F. Reaney, W. S. J. Shaw, G. Tate, and M. H. Thornely.

As is now the rule at this most pleasant and cordial of dinners there were no speeches. Surgeon-General Hay gave the toast of "The King" in a sentence, and introduced in another sentence as the guest of the evening Sir O'Moore Creagh, the new Commander-in-Chief in India. Sir O'Moore Creagh's remarks were brief as well as felicitous, and the company then resolved itself into an informal and delightful meeting of old friends. Mr. P. J. Freyer (Colonel, I.M.S., retired) earns the thanks of the service for the excellent way in which the annual dinner is organised by him.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on Wednesday, June 16th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The following list of lecturers was announced:—Dr. Joseph Shaw Bolton, Goulstonian lecturer; Professor W. Osler, Lumleian lecturer; Professor Sir T. Clifford Allbutt, Fitz-Patrick lecturer; Dr. F. W. Mott, Oliver-Sharpey lecturer; Dr. Wm. Bulloch, Horace Dobell lecturer; Dr. Frederick W. Andrewes, Croonian lecturer (vice Dr. A. Gamgee, deceased); and Dr. Henry Head, Croonian lecturer for 1911.

The REGISTRAR (Dr. E. LIVEING) thanked the President, Sir W. S. Church, and the Senior Censor (Dr. Norman Moore) for the kind way in which they had spoken and the proposals they had made at the last Comitia, and he also thanked the Fellows for the manner in which they had received those proposals.

The College seal was affixed to an address to the University of Cambridge on the Darwin Centenary.

The following communications were received: 1. From the Secretary of the Royal College of Surgeons of England, dated June 11th. 2. From the Rev. J. G. Geare of Farnham Rectory, Bishop's Stortford, asking leave to have a photograph of the portrait of Dr. Richard Hale (1670–1728) in possession of the College. Permission was granted.

Sir W. S. Church was appointed a representative of the College on the Court of Governors of the new University of Bristol.

A report was received from the representative of the College on the General Medical Council on the proceedings of the Council at its May session.

The PRESIDENT then dissolved the Comitia.

PRIZE-GIVING DAY AT HOSPITAL MEDICAL SCHOOLS.—Medals and prizes won during the past year will be distributed to the students of Guy's Hospital by His Grace the Duke of Devonshire at a garden party on Thursday, July 8th, at 3.15 P.M. At St. Thomas's Hospital the prizes will be distributed to the students by the Right Hon Alfred Lyttelton, K.C., M.P., in the Governors' Hall, on Friday, June 25th. At the London (Royal Free Hospital) School of Medicine for Women Lady Northcote will present the prizes and certificates to students for 1908-09 on Friday, July 2nd, at 4 P.M. Mrs. Garrett Anderson, M.D., will take the chair. At King's College the prizes and certificates will be distributed on June 30th by Dr. H. A. Miers, F.R.S., Principal of the University of London.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 18th, 1831.

DAILY DISCHARGE OF OIL FROM THE BOWELS, AND SUGAR FROM THE URINARY PASSAGES.

There is likewise an extraordinary case in Jacob's Ward—a case I have never seen above once or twice before, and never to such an extent; it is the case of a man discharging oil from the intestines. He is labouring under diabetes also—discharging, therefore, sugar from his urethra, while, from his rectum, he pours forth oil. The case must be very interesting to chemists, on account of such a double manufacture going on; and some of our most eminent chemists—four indeed of as good chemists as are in this country, have had specimens of the oil, and they find it to be genuine oil. After a motion it flows from him liquid, and then concretes on the fæces on cooling. Of course you have all seen it swimming in the liquid contents of the vessel, of the colour of unblanched bees-wax.

A case of this kind is mentioned by Mr. Howslip, and, he says, the lady took a pint of oil, and so made no more oil. Though this looked like casting out devils by Beelzebub, yet, as I did not know what to do, I seized the fact, and gave this man six ounces of olive oil to drink; he took two ounces of it, and was sick; he took the remainder afterwards, and it staid down. He has certainly produced very little oil since. Whether that is the consequence of the oil he took or not, I do not know. He has phthisis, too, and he is thus producing a third preternatural fluid pus. Of course he must die; he has been inhaling chlorine with great advantage. It has been gradually diminishing his expectoration. He is sinking under his combined diseases, but he has now hardly any sufferings—none but his cough. I may mention that he at first began by inhaling iodine, but coughed so severely on taking the most minute quantity, even a drop, that I was obliged to give it up. The chlorine he bears well; the amount of many drops, and is greatly relieved by it.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8972 births and 3962 deaths were registered during the week ending June 12th. The annual rate of mortality in these towns, which had been equal to 14·7, 13·9, and 12·3 per 1000 in the three preceding weeks, increased again slightly to 12·6 in the week under notice. During the first ten weeks of the current quarter the death-rate in these towns averaged 14·6 per 1000; the rate in London during the same period did not exceed 14·1. The lowest recorded annual death-rates in these towns last week were 3·2 in King's Norton, 6·1 in Hastings, 6·4 in Tottenham, and 6·5 in Hornsey; the rates in the other towns ranged upwards, however, to 20·7 in Oldham, 21·1 in Stockport, 23·1 in Warrington, and 23·6 in St. Helens. In London the recorded death-rate last week did not exceed 12·2 per 1000. The 3962 deaths from all causes in the 76 towns last week showed an increase of but 68 upon the exceptionally low number in the previous week, and included 391 which were referred to the principal epidemic diseases, against 414 and 360 in the two preceding weeks; of these 391 deaths, 185 resulted from measles, 56 from diarrhœa, 55 from whooping-cough, 42 from scarlet fever, 40 from diphtheria, and 13 from "fever" (principally enteric), but not one from small-pox. The 391 deaths from these epidemic diseases last week were equal to an annual rate of 1·2 per 1000, against 1·3 and 1·1 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Brighton, Southampton, Preston, York, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 4·0 in Wolverhampton, 4·5 in Salford, 4·6 in Norwich, and 5·2 in West Bromwich. The fatal cases of measles in the 76 towns, which had been 178 and 140 in the two preceding weeks, rose to 185 last week, a higher number than in any week since the early part of May; the fatal cases of this disease caused annual death-rates last week ranging upwards to 3·0 in Salford, 3·7 in West Bromwich, 4·0 in Wolverhampton, and 4·2 in Norwich. The 56 deaths attributed to diarrhœa corresponded with the number in the previous week, and were proportionally most numerous in Hanley and Rhondda. The 55 deaths from whooping-cough showed a further considerable decline from the numbers in recent weeks; the highest recorded death-rate from this disease last week was 1·5 in Middlesbrough. The 42 fatal cases of scarlet fever were within three of those returned in the previous week, and included 12 in London and its suburban districts, three in Liverpool, eight in Manchester and Salford, and two in Oldham. Of the 40 deaths from diphtheria, showing a slight increase upon the numbers in the two previous weeks, nine occurred in London and its suburban districts, four in Birmingham and its suburbs, seven in Manchester and Salford, and two both in Bradford and in Merthyr Tydfil. The deaths referred to "fever," which had been 20, 16, and 11 in the three preceding weeks, were 13 last week. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2254 and 2223 at the end of the two preceding weeks, had increased to 2263 on Saturday last; 395 new cases of this disease were admitted to these hospitals during last week, against 348, 335, and 273 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 225 and 172 in the two previous weeks, further declined last week to 152 and were 15 below the corrected average number in the corresponding week of the five years 1904–08. The deaths in London referred directly to influenza were 13, showing an increase of three upon the number in the previous week. The causes of 25, or 0·6 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during the week were again duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, Salford, Hull, and in 52 other smaller towns; the 25 uncertified causes of death included five in Liverpool, five in Birmingham, and two each in St. Helens, Coventry, and Willesden.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 957 births and 518 deaths were registered in the week ending June 12th. The annual rate of mortality in these towns, which had been equal to 17·5, 16·7, and 16·3 per 1000 in the three preceding weeks, further declined to 14·5 in the week under notice. During the first ten weeks of the current quarter the death-rate in these Scotch towns averaged 16·7 per 1000, while in the 76 large English towns the mean death-rate during the same period did not exceed 14·6. The death-rates last week in these Scotch towns ranged from 11·6 and 12·3 in Leith and Greenock to 15·9 in Glasgow, and 19·9 in Paisley. The 518 deaths from all causes in the eight towns showed a further decline of 64 from the numbers returned in recent weeks, and included 55 which were referred to the principal epidemic diseases, against 76, 68, and 59 in the three preceding weeks. These 55 deaths were equal to an annual rate of 1·5 per 1000, against 2·1, 1·9, and 1·7 in the three previous weeks; the mean death-rate last week from these principal epidemic diseases in the 76 large English towns did not exceed 1·2 per 1000. Of the 55 deaths from these epidemic diseases last week in the Scotch towns, 22 resulted from whooping-cough, 15 from diarrhœa, five from "fever," five from scarlet fever, five from diphtheria, and three from measles, but not one from small-pox. The fatal cases of whooping-cough in the eight towns, which had been 40 and 25 in the two preceding weeks, further declined to 22 last week, of which 13 occurred in Glasgow and eight in Edinburgh. The 15 deaths attributed to diarrhœa corresponded with the number in the previous week, and included five both in Glasgow and in Aberdeen, and four in Dundee. The five deaths referred to "fever" also corresponded with the number in the previous week, and were all recorded in Glasgow; three were certified as enteric and two as cer[illegible] the five fatal cases of scarlet [illegible]: while of the five deaths from [illegible] of two from the number in the previous week, two were returned in Glasgow and two in Leith. The three deaths from measles all occurred in Paisley. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 109, 94, and 93 in the three preceding weeks, further declined to 80 last week, but exceeded by 29 the number in the corresponding week of last year. Of the deaths in the eight towns, 21 resulted from violence, including 13 in Glasgow and four in Edinburgh. The causes of 12, or 2·3 per cent., of the deaths in the eight towns last week were unspecified or uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

---

[1] Excerpt from Clinical Lecture delivered by Dr. Elliotson at St. Thomas's Hospital on March 31st, 1831.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 22·3, 21·7, and 18·2 [illegible] weeks, rose again to 18·7 in [illegible] During the first ten weeks of [illegible] rate in the city averaged 21·8 per 1000, whereas the mean rate during the same period did not exceed 14·1 in London and 16·3 in Edinburgh. The 143 deaths of Dublin residents from all causes during last week showed an increase of four upon the number in the previous week, and included nine which were referred to the principal epidemic diseases, against 13 and 11 in the two preceding weeks. These nine deaths were equal to an annual rate of 1·2 per 1000, the death-rate from these epidemic diseases in the same week being 1·3 in London and 1·2 in Edinburgh. Of the nine deaths from these epidemic diseases in Dublin last week, four resulted from whooping-cough, two from "fever," and one each from measles, scarlet fever, and diarrhœa, but not one either from diphtheria or small-pox. The fatal cases of whooping-cough corresponded with the number in the previous week. The 143 deaths included 23 of infants under one year of age and 39 of persons aged upwards of 60 years; the deaths of infants showed an increase upon the low number in the previous week. Three inquest cases and two deaths from violence were registered last week, and 65, or 45·5 per cent., of the deaths occurred in public institutions. The causes of four, or 2·8 per cent., of the 143 deaths registered in Dublin last week were not certified either by a registered medical practitioner or by a coroner; all the causes of the 1135 deaths registered in London last week were duly certified, whereas in Edinburgh the proportion of uncertified causes of death was equal to 3·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: T. H. Vickers to the *Victory*; R. Hughes to the *Cressy*; F. F. Lobb to the *Antrim*; J. E. H. Phillips to the *Sappho*; R. F. Clark to the *Sirius*; E. Arkwright to the *Natal*; R. S. Bernard to the *Edgar*; and M. O. Langford to the *Hawke*. Surgeons: G. S. Davidge to the *Diamond*, additional, for the *Tyne*; E. L. Atkinson to the *Achilles*, on completing; and M. W. Haydon to the *Cormorant*, additional, for Ascension Hospital.

INDIAN MEDICAL SERVICE.

The Ki[illegible]wing promotions among officers c[illegible]vice:—To be Colonel: Lieutena[illegible] Steel Lyons (dated Jan. 13th, 1909). Majors to [illegible] March 30th, 1909): Fairlie [illegible] Steel Anderson, John Telfe[illegible] Percival Ricketts, Charles Ma[illegible] Arthur Gervase Hendley, Georg[illegible] Tilson Hudson.

His Majesty has also approved of the retirement of the [illegible] Damodar Purshotam [illegible]: Major Charles Henry [illegible]

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st London (City of London) General Hospital: To be Captains, whose services will be available on mobilisation: Frederick William Andrewes (dated May 25th, 1909). Walter Langdon Brown (dated May 25th, 1909).

2nd London Sanitary Company: John Muir to be Lieutenant (dated May 5th, 1909).

For attachment to Units other than Medical Units.—Lieutenant John Paton to be Captain (dated Feb. 16th, 1909). The promotion to a Majority of Captain Edmond U. F. MacW. Bourke bears date Sept. 28th, 1908. Captain Frank Grégoire Proudfoot, from the 3rd Southern General Hospital, to be Captain (dated May 1st, 1909). David Gerald Kennard to be Lieutenant (dated May 17th, 1909).

VOLUNTEERS.

Royal Garrison Artillery:—5th Lancashire: Surgeon-Captain Thomas W. Butcher resigns his commission (dated March 31st, 1908).

QUEEN ALEXANDRA ROYAL MILITARY HOSPITAL.

It is officially announced that the King will be present at the opening service of the new chapel of the Queen Alexandra Royal Military Hospital, Millbank, on Thursday, June 24th.

Correspondence.

"Audi alteram partem."

THE CAUSATIVE FACTOR OF BERI-BERI.

To the Editor of THE LANCET.

SIR,—I have read with great interest your report of the meeting of the Society of Tropical Medicine and Hygiene (May 21st), and as I gather from it that there is still a marked prejudice against Dr. W. L. Braddon's theory as to the causation of beri-beri, I should like to put on record two concrete examples of outbreaks of the disease, which I think go far to prove his case.

The first is the history of an epidemic of *true* beri-beri occurring on a cable-repairing steamer belonging to the Eastern Telegraph Company, and stationed in the Red Sea, and I think it is an important point that no case of the disease had occurred on this particular ship for at least three years previously. On May 24th, 1907, a crew of 50 Lascar [illegible] cooks are excluded because [illegible]

At the end of July the last bag of this particular rice was expended, and as the ship was now working on her station in the Red Sea a supply of Rangoon "uncured" rice was picked up at Aden and replenished later at Suez. This rice began to be consumed during the last week in July and was the staple article of diet until [illegible] outbreak of beri-beri occu[illegible] by the ship's surgeon, but [illegible] of the Indian Medical Service stationed at Aden, where a number of the men were landed in hospital. Altogether there were 20 well-marked cases, of whom three died, and as the others were probably infected, the whole crew were shipped backed to Bombay and a fresh one sent to take its place.

About this time I came across Dr. Braddon's book, and being much impressed by it I considered that this epidemic was a vindication of his theory. The men had been perfectly healthy whilst Indian rice was consumed and the outbreak did not commence till Rangoon rice had been in use for three months, which I gather is the usual period. Here [illegible] effect had seemed [illegible] hesitation in advisi[illegible] stop the supply of [illegible] stitute the "cured" variety as a permanent institution. This advice was acted upon at once, and I can now place it on record that with the same class of crew, living under exactly the same conditions, not one single case has occurred since.

The other concrete example, to which I would like to draw attention, deals with the history of two epidemics of beri-beri occurring amongst the Chinese coolies employed in erecting buildings on a small island in the Cocos-Keeling group for the Eastern Extension Telegraph Company. The first outbreak was in 1902, when I myself was in medical charge. It was very virulent and in spite of all precautions as to sanitation, treatment, moving the site of the coolie lines on two occasions, &c., 48 cases occurred amongst 60 men, and of these 17 died. At that time many conflicting opinions as to the cause of beri-beri were held by the medical authorities in the Straits Settlements, and those whose opinion seemed to carry the greatest weight did not believe in the rice theory. I therefore discounted it, but was able to come to no conclusion that satisfied me. I thought that an early case had been overlooked when the men were inspected in Singapore and that the others had become infected from this, but in view of recent research and with the dates and history of the epidemic before me I am firmly of the opinion that it was due to the consumption of "uncured" rice. Against my idea of an infection was the fact that no single case occurred amongst the cooks and house servants, and as these had less rice and a more generally generous diet, it is really a distinct point in favour of Dr. Braddon's theory.

Following this epidemic the work was rapidly finished by a large new gang and no more was heard of beri-beri on the island till March, 1908, when the same conditions as before were repeated. New buildings were required and a gang of 68 Chinese coolies left Singapore on Jan. 2nd, taking with them the usual Chinese food-supplies, of which the staple was "uncured" rice. The medical man in charge was Mr. A. H. Macdonald, whose work, during a very trying time, was most excellent and from whom we received long and careful reports. The epidemic began with a case on Feb. 18th followed by another on the 29th. Then six cases developed between March 6th and 30th, and during April it became a scourge, no less than 34 further cases being added. On May 1st three more developed, and of this total of 45, 12 died on the island and three others whilst on their way back to Singapore. The whole of the remaining men were taken away from the island on May 2nd and were replaced immediately by a new gang of 29 which arrived on April 28th and whose number was further increased to 45 on July 2nd. This new gang were housed in new huts and all possible precautions taken, but the only real difference in their work, environment, and diet was that the rice-supply, on my strong recommendation, was changed from the "uncured" to the "cured" variety.

The result is both interesting and instructive. Writing under date June 29th, 1908, Mr. Macdonald says: "The new gang has been, and still is, in excellent health, not one having been absent from work a single day through illness," and again, under date Sept. 25th, 1908, he states, "The Chinese workmen have had no sickness amongst them beyond minor surgical troubles." Discussing the probable cause of this immunity from beri-beri, he states that he considers *the strongest factor* is the substitution of "cured" for "uncured" rice, and with this I fully agree. The greater number of this gang of workmen left the island on Oct. 1st, not a single case of beri-beri having occurred amongst them, and I attribute this solely to the fact that a general order has been in force since April, 1908, that no "uncured" rice is to be supplied to the native servants of the company (Chinese or Malay) working on this island.

Reviewing the history of these three epidemics, it seems to me that Dr. Braddon's work marks a great epoch in the study of a disease, the ravages of which must be seen to be believed, and if these details will induce others to put his theories into practice I feel sure they will be gratified with the results.—I am, Sir, yours faithfully,

C. W. CURTIS, M.R.C.S. Eng., &c., D.P.H.,
Principal Medical Officer, Eastern and Associated Telegraph Companies.
Electra House, E.C., June 12th, 1909.

COLOUR VISION IN THE MERCANTILE MARINE.

To the Editor of THE LANCET.

SIR,—The long time it takes to awaken certain official bodies out of the lethargy into which their official position lulls them is notorious, but it is surely time that the Board of Trade undertook to revise the methods they use for the examination of candidates to whom they grant certificates of proficiency in colour vision when these men have thousands of pounds worth of property and hundreds of lives dependent upon their correct appreciation of coloured lights which are constantly appearing during the night at sea, and who likewise have to read signals made with coloured flags during the daytime. The methods still in vogue are "Gilbertian" to a degree and would scarcely be credited by a stranger unacquainted with certain official methods. This state of affairs was prominently brought forward only a few weeks ago.

It appears that a Mr. —— obtained his certificate as second mate 18 months ago, when he was examined for colour vision by a certain captain in the Mercantile Marine appointed by the Board of Trade for this obviously medical duty, and he was duly passed. After serving for another period at sea he presented himself for examination as "mate," when the same examiner tested his sight and rejected him on account of defective colour vision. Not content with this, the candidate applied for a "special examination," in consequence of which the Board referred him to their special examiners, who consisted of another ship's captain assisted by an assistant professor of physics at the Royal College of Science. These examiners, who, of course, had no knowledge of ophthalmology or physiology, confirmed the previous decision and rejected him. He next on his own initiative applied privately to an ophthalmic surgeon, who found his colour vision so good that it in no way impaired his efficiency as an officer at sea. This, of course, was distinctly awkward for the Board of Trade, who had somehow to get over the difficulty, so in their wisdom they appointed a special tribunal to decide between the doctor and the lay examiners. One would have expected that this tribunal would have been composed of specialists in eyesight, or at any rate of people who knew something of the subject in order to weigh the conflicting evidence. Although such a course would be natural, yet it is not the way of the Board of Trade, who have ideas of their own on such matters, so they appointed the president of the local Marine Board, a stipendiary magistrate, a Member of Parliament, and one or two ship's captains.

Considering that not a single member of this committee had any more knowledge of physiology and sight-testing than had the original examiners, it is obvious that any opinion they might express as to who was right and who was wrong would not be worth the paper on which it was recorded, and an equally satisfactory result would have been arrived at by the simple expedient of tossing a coin and seeing whether it came down heads or tails. Still one must give credit where it is due, and this tribunal not unnaturally came to the conclusion that the doctor was more likely to be right on a medical point than superannuated captains, and so they decided that the candidate had good colour vision, and that his certificate should be granted. Would anyone believe that in the present day such a farce would be gravely carried through by a responsible Government department, and yet this is absolutely what happened about four weeks ago.

In this letter it would be impossible to go into the details of this ridiculous affair, but suffice to say that the important lantern test was used by no one. Holmgren's wools were, of course, used, and everyone knows how utterly impossible it is to detect all cases of colour-blindness with them. Brilliant spectral lights were employed for an abnormal length of time, and this no doubt produced fatigue, and after-images which would render anyone incapable of correctly naming the colours seen, and as these are pure colours and not impure ones (as is always the case with signal lanterns) so we find those with defective colour sense far more confused by the impure colours than by the pure ones, and thus it is that an examination with spectral lights is by no means a good test to rely on in a routine examination. Colour fatigue is far more readily produced in those whose colour vision is below the normal, but there are scores of people who although not possessing the most highly developed colour sense yet would never mistake a colour used in a signal lantern, and it would be as unfair to reject these as it would be to call a person deaf whose ear was incapable of distinguishing quarter tones in music.

These unhappy candidates are at the present time at the mercy of a board who seem incapable of grasping the fact that an examiner should have some knowledge of the subject on which he is asked to adjudicate. Surely there are plenty of ophthalmologists in the land, and if there are, why cannot some of them be appointed to examine eyesight? We shall next hear of mining engineers examining candidates in navigation, or sanitary inspectors granting certificates for proficiency in marine engineering. The way in which this particular candidate was tested clearly shows that they were attempting to use some of the methods so long advocated by Dr. Edridge-Green, but that having no knowledge of the subject they utterly failed to grasp his points, and thus we find a man who, but for his perseverance, would have had his livelihood taken away from him, just because of some antiquated regulations to which the Board of Trade still adhere. It is to be hoped that before long this crying injustice both to the candidates and to the general public will be swept away, and that common sense will at last prevail. It is surely no great thing to ask that the Board of Trade shall appoint as their examiners men who know something about their subject.

I am, Sir, yours faithfully,

Harley-street, W., June 7th, 1909. C. DEVEREUX MARSHALL.

A CASE OF SEVERE VERTIGO AND TINNITUS; DESTRUCTION OF THE LABYRINTH; CURE.

To the Editor of THE LANCET.

SIR,—Under the above heading I published in THE LANCET of Sept. 19th, 1908, p. 871, a case which that title sufficiently describes. As a year has now elapsed since the operation, it may be of interest to your readers to know the further history of the case. I wish also to correct a slight error in the early history of the patient. It is stated in the account given that he had been "free from discharge for over 18 years"; as a matter of fact, the discharge occurred in infancy and ceased before the age of eight years, the patient being 48 years and 6 months old at the time of the operation.

I last saw the patient on May 28th of this year—the first anniversary of his operation. The wound cavity in the left temporal bone was soundly healed and completely epithelialised, the scar of the incision being scarcely visible. The hearing was *nil*. The patient expressed himself as feeling "better than he had been for years." He has had no tinnitus and no vertigo whatever since his operation, and is able to carry out his duties as a country clergyman without the least trouble; he is, of course, greatly helped by his proficiency in lip-reading. The condition of his vestibular apparatus was investigated for me very kindly by Dr. Dan McKenzie, the result of his examination being as follows: "Slight nystagmus both, slightly more marked left. Caloric cold, L., spontaneous nystagmus unchanged in 120 secs. No vertigo. Caloric cold, R., (?) increase of spontaneous nystagmus in 90 secs. No vertigo."

Nine days before his operation the hearing in the right ear was: voice, whisper, acoumeter, Galton whistle, bone conduction (to C128), *nil*. By air conduction he showed perception for C^2, C^3, and C^4. He perceived the continuous tone series a^2 to a^3, but missed C_4 sharp. After the operation, the hearing in the right ear improved very slightly, being on June 29th, 1908: voice 3 inches; Galton whistle, 11048·30 D.V.; bone conduction (C123), 0. By air he showed: 1064 perception (?), C perception, C^1–27″, C^2–38″, C^4–19″, C^4–35″, but this increase is now slightly diminished.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY, F.R.C.S. Eng.

Harley-street, W., June 15th, 1909.

THE NEW IRISH UNIVERSITIES.

To the Editor of THE LANCET.

SIR,—In a fortnight the statutes of the new Irish Universities will have passed into law, so that any modifications must be made by Parliament at once. Convocation of the Royal University—largely composed of medical men—has not been consulted about these statutes, and therefore they need amendment. The Convocation recommended the establishment of a degree of B Sc. in Public Health. This has been done in Dublin but not in Belfast, but instead of being open to graduates of all universities on the Medical Register is confined, apparently, to those who have taken the M B in the University at Dublin. It is also complained that an effort is being made to shear Convocation of any real strength by confining the power to call meetings of it to the Chancellor or Senate in Dublin, whilst in Belfast a number of members can call a meeting of Convocation. Power to elect a clerk of Convocation has hitherto lain with that body. Now it is transferred to the Senate.

Hitherto Convocation of the Royal University elected a certain proportion—usually of medical men—to the Senate. This power is now taken from them for five years. There is also a strong objection to persons who have been nominated members of the Senate of the new universities being elected to paid professorships or other posts of emolument. If such are elected they should resign from the Senate forthwith. The institution of a degree of D.Sc. in veterinary medicine is desirable; there is a strong Veterinary College in Dublin, but no provision for the study of diseases transmissible from animals to men. Such post-graduate study would be the result of the possibility of obtaining a higher qualification for a veterinary surgeon. In like manner a much-needed stimulus to the study of pharmacology would result from the granting of a B.Sc. degree in pharmacology for registered pharmacists. I am, Sir, yours faithfully,

J. C. McWALTER, M.A. R U.I,
M.D. Brux., F.F.P.S. Glasg.

Dublin, June 13th, 1909.

PS.—Unless power is given to the statutes to confer these new degrees Convocation will be unable to do so afterwards.

CEREBRAL HÆMORRHAGE AND HYPERPYREXIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 12th, p. 1716, you published a letter from Dr. Morgan Richards relating to a case of cerebral hæmorrhage followed by hyperpyrexia and death, which occurred on board the Pacific Company's R.M.S. *Oropesa*. By a strange coincidence I had a similar experience, curiously enough on the same boat and in practically the same part of the Atlantic. A passenger, aged 35 years, who previously to his death looked to all intents and purposes a healthy man, was one morning "seized with a fit" when about three days' journey from St. Vincent. The heat had been very trying and when I saw him he was in the usual condition seen in cerebral hæmorrhage, cyanosis, stertor, coma, &c. When examining him I was struck with the extraordinary heat given out by the body, and on taking the temperature in the axilla I found it 110° F.; in fact, the mercury had gone right up to the end of the thermometer. On procuring another instrument graduated to 115° I found the temperature in the axilla was 111° and in the rectum 111·5°. The patient died four hours after the seizure. Hyperpyrexia before death is quite a common accompaniment of cases of cerebral hæmorrhages and in injuries to the head, and in reply to your correspondent, Mr. V. P. Norman, this phenomenon seems to me to be a clinical fact quite often recorded. I am, Sir, yours faithfully,

B. H. PALMER, M.B., B.C. Cantab.

Victoria Hospital, Folkestone, June 14th, 1909.

BLOOD EXAMINATION IN SUSPECTED APPENDICITIS.

To the Editor of THE LANCET.

SIR,—In the interesting case of appendicitis reported by Dr. J. S. Boden and Mr E. M. Corner in THE LANCET of June 12th, p. 1682, it seems to me that had a blood count been made on the same day (Jan. 28th) as the blood specimen showed a negative typhoid reaction a diagnosis of suppuration could have been made. On the 26th the blood count would probably have indicated the presence of pus, and I am inclined to think that a leucocytosis would have been found on the 23rd or possibly even on the 22nd. It is evident that very little would have turned the balance in favour of early operation, and an increased white cell count, so rarely found in typhoid fever, would have been sufficient. One has not to wait for a large abscess before getting the blood change—a single drop of pus is sufficient, as was found in a case I operated on lately where the white cells numbered 35,000 per cubic millimetre and where the ovaries and tubes were much swollen and adherent, and a single drop of pus was found in the appendix. Sufficient attention has not been drawn to the necessity for counting the blood cells in all cases where suppuration is a possibility.

I am, Sir, yours faithfully,
June 14th, 1909. SKENE KEITH.

LENHARTZ'S TREATMENT OF GASTRIC ULCER.

To the Editor of THE LANCET.

SIR,—In the account given by Professor Lenhartz of his treatment of gastric ulcer in your report of the German Congress of Internal Medicine in THE LANCET of June 12th, p. 1716, he says that 40, and subsequently 50, grammes of raw meat are given per day. A little later he says that the patient is not discharged from hospital until no blood has been present in the fæces for several weeks. It is important and would be interesting to know what diet Professor Lenhartz keeps his patient on for the few days previous to the examination of the fæces, and how often this is done.

I am, Sir, yours faithfully,
College Gardens, Belfast, June 14th, 1909. W. CALWELL.

⁂ Our correspondent will find the treatment of Professor Lenhartz set out at length with a diet table in an article by Dr. J. Victor Haberman which was published in THE LANCET of July 7th, 1906, p. 25. But the examination of the fæces is not mentioned.—ED. L.

THE SEMON TESTIMONIAL.

To the Editor of THE LANCET.

SIR,—Sir Felix Semon, physician-extraordinary to the King, is retiring from practice, and the occasion will be marked by a complimentary banquet to be given him by his professional and other friends on Friday, July 2nd, at the Whitehall Rooms, Hotel Métropole. The organisers of the banquet are anxious to found a lectureship or scholarship in his name to be a record of his scientific work as one of the founders of the British School of Laryngology. Mr. Henry T. Butlin will preside at the dinner, and all communications with regard to the Testimonial Fund or application for seats at the banquet should be addressed to one of us, the honorary secretaries.

We are, Sir, yours faithfully,
ALFRED MOND, M.P.,
35, Lowndes-square, S.W.;
P. WATSON WILLIAMS, M.D. Lond.,
4, Clifton-park, Bristol;
H. J. DAVIS,
8, Portman-street, London, W.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

(*Concluded from p. 1718.*)

The Treatment of Chronic Bronchitis and Bronchial Asthma by X Rays.

Dr. SCHILLING (Nuremberg) reported that he had obtained excellent results by the use of x rays in chronic bronchitis and bronchial asthma. The discharge became less abundant and the asthmatic trouble became better or even disappeared. In some instances the asthmatic attacks were definitely stopped by a single application of the rays. The results were especially striking in children. In 70 per cent. of the cases complete recovery, or at least great improvement, took place. The improvement continued in a great number of cases for months and even for years.

Neurasthenia after Lead-poisoning.

Dr. OTTO NAEGELI-NAEF (Zürich) reported an epidemic manifestation of neurasthenia in workmen suffering from lead-poisoning. The objective symptoms of poisoning were very slight, but characteristic symptoms of neurasthenia were present, having the appearance of a traumatic neurosis.

Researches on Metabolism in Febrile Diseases and Convalescence.

Dr. ROLLY (Leipsic), after alluding to some observations formerly made by him on metabolism in patients suffering from enteric fever, reported a new series of researches in infectious diseases carried out in conjunction with Dr. Meltzer. The cases included 7 of septicæmia, 4 of angina, 1 of catarrhal pneumonia, 1 of rheumatic arthritis, 1 of erysipelas, and 2 of tuberculosis. The results were very like those obtained in enteric fever, in the feverish stage as well as in convalescence. He further found in two patients suffering from anæmia and gastric ulcer and in a patient suffering from pernicious anæmia that in these cases a chemical substance containing much oxygen was retained in the organism. He concluded that in morbid conditions leading to inanition, whatever the cause might be, the albumin of the body was oxidised in an abnormal way, so that the nitrogenous part was at once consumed, whilst the component consisting partly of carbon was retained in the body for a long time. This carbon-containing compound was eliminated through the lungs during convalescence whilst the nitrogen was again assimilated.

The Metabolism of the Inorganic Constituents of the Tissues in Relation to Pathology.

Professor MAGNUS-LEVY (Berlin) said that the theory o ionisation made it possible to understand how substances of inorganic origin might enter into chemical combination with organic compounds. This process, in which inorganic substances acquired properties not possessed by them when in the free state, was, in fact, rather frequent. The mineral substances which were necessary for the organism were contained in the food, and when they were not already in a state of organic combination the body was able to convert them into organic compounds. A classic example was the inorganic iron which entered into the composition of hæmoglobin. According to the opinion of Professor Bunge the administration of iron was useless for the formation of hæmoglobin, but clinical experience has, nevertheless, shown that this opinion was erroneous, and by experiments in animals it had been proved that ferrates, and even metallic iron, in a state of fine division, were assimilated by the organism. With respect to calcium the speaker pointed out that the rachitis of children was not exclusively caused by a deficiency of calcium salts in the food; it had been shown by experiments on young animals that the administration of food containing no calcium salts produced a morbid condition clinically similar to rachitis, but that the microscope revealed the existence of histological differences. The deficiency of lime in the food might, however, produce a liability to rachitis. In chronic exhausting diseases such as leukæmia and diabetes there was weakness of the bones together with an abundant excretion of phosphates. Professor Magnus-Levy made only a short allusion to compounds containing iodine because that question had been discussed in this Congress two years ago, and he then took up the subject of chloride of sodium. He said that a daily quantity varying from 15 to 20 grammes of this substance was harmless for healthy persons because it was discharged by the urine within 24 hours, but when the kidneys were in a morbid condition they were unable to eliminate that amount and a retention of salt consequently occurred. This retention was frequently the cause of œdema. A reference was made to Professor Widal's observation that the œdema from which a patient was suffering disappeared as soon as no chloride of sodium was given with the food, but re-appeared on the administration of ten grammes of the salt. A strict milk diet was not advantageous in these conditions, because three litres of milk contained five grammes of common salt, but a mixed food, consisting of bread, potatoes, rice, butter, and some meat, contained only from one to two grammes of salt, provided that no salt was added in cooking the food. Under the *régime achloruré* of Professor Widal excellent results had been obtained in cases of Bright's disease attended with œdema. The retention of phosphates did not produce œdema. Œdema in diseases of the heart and liver depended on other causes and were therefore not so decidedly influenced by the food, but nevertheless some good results were obtained by similar treatment. Retention of chloride of sodium occurred in arterio-sclerosis, gout, emphysema, and in all acute infectious diseases; a reduction of the amount of common salt in the food might therefore be useful in these conditions. In the treatment of epilepsy, if food containing little chloride of sodium was given, this had the effect that an alkaline bromide administered therapeutically was retained in the system, so that its specific action on the disease was of longer duration. In infants morbid conditions were frequently produced by a too liberal use of common salt.

Therapeutic "Dechloruration."

Professor WIDAL (Paris) gave an historical review of the observers who have contributed to the modern theory of the action of chloride of sodium in Bright's disease. He said that some authorities had held the opinion that this was not the only substance which was of importance for the development of œdema. Professor Widal, however, together with Dr. Faval, maintained that chloride of sodium alone was the cause of this symptom; they succeeded in producing œdema in Bright's disease by administering a certain quantity of salt in the food. He further stated that milk was too rich in salt for such patients, and that a mixed diet as above mentioned by Professor Magnus-Levy in his address contained a smaller proportion of salt and was therefore more suitable. Œdema occurred in two stages, first in the form of deep infiltration, which was not visible, and, secondly, as visible œdema of the skin and subcutaneous tissue. Deep infiltration could only be ascertained by regularly weighing the patient. The method of dechloruration devised by Professor Widal had two objects—namely: (1) to remove the salt contained in the organism and so to combat the œdema; and (2) to ascertain the amount of salt which could be discharged by the diseased kidney. It must be remembered that the permeability of the kidneys for salt was different in different individuals and in different stages of the disease. By observing the patient's weight and the relative quantities of salt ingested and excreted it was possible to ascertain the amount which was suitable for the organism. In certain patients dietetic treatment alone had not the desired effect and diuretic medicines must be administered. When the œdema had disappeared, [illegible] of the patient had been constant for several [illegible] reased. [illegible] others the method was no longer suitable after a certain time. The [illegible] forms of Bright's disease—one [illegible] the other with retention of [illegible] was retained in the blood, whilst the chloride of sodium made its way from the blood into the tissues of the body. Therefore the retention of salt often leads to hydropic uræmia, the retention of urea to dry uræmia. In patients suffering from retention of salt the urea might be present within the blood only in a minimal quantity of 0·2–0·5 gramme for every litre, but when the blood contained up to 4 grammes of urea a retention of urea was present. Certain patients with vomiting and symptoms of apparent eclampsia and œdema might improve very soon, whilst others showing only a slight sleepiness or anorexia might suddenly fall into deep coma. In these cases the prognosis might be ascertained by the quantitative estimation of urea; notwithstanding severe symptoms good results were obtained by dechloruration when the quantity of urea was normal, which meant that only a retention of chloride of sodium was present. Patients with Bright's disease, even without insufficiency of the kidney, should take as little salt as possible, because it was impossible to state at what moment an abundant administration of salt might become harmful.

Professor STRAUSS (Berlin) spoke against dechloruration in Bright's disease with a good compensation of the kidneys. In œdema issuing from heart disease only in very severe cases a result may be obtained with dechloruration.

Dr. BICKEL (Berlin) discussed the influence of mineral substances on the glands of the stomach. He said that the same mineral substance might have a different action on the healthy or morbid viscera. Some of them produced an increase of secretion within the stomach, but a decrease in the intestines.

Dr. KLUM (Strasburg) said that the administration of a great quantity of bicarbonate of soda produced œdema by the retention of water, especially in diabetic patients. He mentioned the case of a diabetic man whose weight increased within six days by 9 kilogrammes after an administration of 190 grammes of bicarbonate of soda. Hitherto this compound was used as a diuretic. Probably in diabetes with acidosis the tissues retained the compound because of the deficiency of salt; the same was the case in healthy people when a diet poor in salt was given.

The Relation Between Internal Secretion and Salt Metabolism.

Dr. FALTA (Vienna) said that a relation existed between the thyroid gland, the pancreas, the hypophysis, the chromaffin system and the metabolism of albumin, carbohydrates, and fat. There were two groups of glands: the first, to which the thyroid and the hypophysis belong, acted on the sympathetic nerves, and was therefore termed the sympathetic group; it increased the [illegible] termed autonomic group, had a [illegible] metabolism, especially of albumi[illegible] antagonism between the two groups was obvious also in the metabolism of salts; the sympathetic glands increase, the autonomous decrease it. In animals the removal of these glands produced an enormous increase of the discharge of salts by the kidneys. Eosinophilia and galvanic irritability were also influenced by both groups of glands in an antagonistic sense.

The Action of Intravenous Injections of Hypertonic Salt Solutions.

Dr. VAN DEN VELDEN (Elberfeld) said that injections of a few cubic centimetres of a 5 to 10 per cent. salt solution had a hæmostatic action. He had never seen any ill effect [illegible]ither fever nor albuminuria nor [illegible] increase of leucocytes. The [illegible]ythrocytes was not altered; a slight hyperæmic plethora and a better filling of the vessels were observed.

In the discussion Professor MOHR (Halle) said that he had tried to produce œdema by the administration of water to animals from which salt had been withheld and which had previously been made artificially nephritic. The experiment was successful in four dogs. He concluded that in the treatment of hydropic patients not only the dechloruration but also the quantity of water was of importance. Dechloruration was not harmless, as suggested by Professor Magnus-Levy and Professor Widal. Two dogs suddenly died on a diet [illegible] sense. In infectious diseases Bright's disease might be avoided by administering a diet with little salt. Professor Mohr had prescribed in 12 cases of scarlet fever the usual milk diet, and in another series of 10 cases meat without salt after Widal's theory. The result was that of the first series six cases and of the second series two cases contracted Bright's disease.

Dr. GERHARD (Jena) drew attention to the sudden alterations of the excretion of chloride of sodium occurring in acute Bright's disease; he saw the discharge of salt stop for one to two days whilst the albuminuria and the discharge of casts continued for weeks. When a retention of water happened in diabetic acidosis after the administration of a large dose of chloride of sodium, a characteristic œdema of the face was often present.

Dr. SCHOTT (Nauheim) said that it was important for the therapeutic effect of dechloruration that the patient should make active movements. The state of the patient sometimes underwent remarkable alteration during dechloruration; whilst the diet was quite suitable to them for a certain time, they might suddenly show anorexia, enormous œdema, and syncope, and these undesirable symptoms might even disappear after the administration of a food with an abundant amount of common salt.

Professor MAGNUS-LEVY, answering the above objections, said that an increase of weight was often observed in diabetic patients after the administration of bicarbonate of soda; it [illegible] the normal amount of wate[illegible] The opinion that dechloru[illegible] healthy kidney was not yet [illegible] the sudden death of Professor Mohr's dogs, he pointed out that such deaths of animals frequently occurred in laboratories without an apparent reason. The cases mentioned by Professor Schott were very interesting, but further analysis of these cases was necessary. Dechloruration as a prophylactic against Bright's disease was not quite reliable.

The Use and Interpretation of Electro-cardiograms.

Professor HERING (Prague) said that he had caused in animals by injections of dioxalic acid an "alternating" action of the heart and showe[illegible] curves taken before and after the [illegible]rnating effect; the heart was shown to beat in an inverse sense, the contraction of the ventricles preceding that of the auricles. It was remarkable that the heart of frogs which had only one ventricle showed the same electro-cardiogram as the heart of mammals, including the human species.

Dr. HOFFMANN (Düsseldorf) said that the electro-cardiographic method might give misleading results from a variety of causes, such as displacement of the heart by pleuritic exudations, gastric flatulence, &c. According to his opinion the electro-cardiographic method does not explain the contractions but the irritability of the heart; it cannot be used for clinical purposes without a solid physiological and pathological basis, which hitherto does not yet exist.

Dr. STRUBELL (Dresden) showed a great many electro-cardiograms of healthy individuals, athletes, and aged persons. He said that tremor of the fingers was one of the principal causes of failures of the method. The curve disappears with the deterioration of the cardiac action. With the use of the electrographic method a new era had commenced in the diagnosis of heart diseases, especially of arrhythmia.

THE CLEANSING OF CAIRO.

(FROM OUR SPECIAL SANITARY COMMISSIONER)

(Concluded from p. 1723.)

FILTHY FUEL FOR PUBLIC BATHS.—VAST ACCUMULATIONS OF GARBAGE AND SCAVENGER CATS IN POPULOUS CENTRES.—BUILDING ON DOMESTIC REFUSE.—STREET CLEANING AND UNRULY EUROPEANS.—FLOODS ON FOUL SOIL.—CONCLUSION.

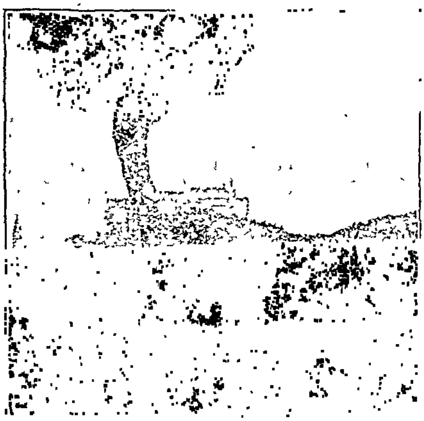
OF the 600 cartloads of rubbish collected in a day, the baths, as already stated, purchase 189 loads. This would be an excellent thing if the rubbish was at once placed in the furnaces that warm the water for the baths and consumed. But under the pretext that if it rained the refuse would not be dry enough to burn the managers of the baths are allowed to store a sufficient supply for at least a fortnight. In reality, they often take in enough to last several months, and such a vast accumulation of very foul refuse creates a great nuisance. It must also be borne in mind that the baths are not in outlying parts but, on the contrary, are distributed all over the city and are more especially to be found in the districts where the population is most dense. My first visit was to the largest and best hammam in Cairo. A narrow street conducted me to the back of the premises and there I had to descend into sombre and sinister regions, stepping on all kinds of indescribable things, slimy and slippery or hard and gritty by turns. And sometimes a twining thing, a piece of wire or the hoop of a broken barrel, would get between my feet or grasp my ankles and threaten to trip me up. We passed by narrow winding passages. There might have been stairs but they could not be seen or felt, for the space between the steps was choked up with the dirt and refuse that had been dropped and trodden into them so that the stairways were converted into inclined planes. Ascending I reached the roofless floor of a ruined house. There seemed to be two or three dilapidated houses just behind the baths and their roofless rooms were filled many feet deep with all the refuse brought up from the scavengers' carts. Dust-besmirched, wretched men groped their way about carrying bags full of this rubbish from the scavengers' carts to these store-rooms or from the store-rooms to the furnace below. There were likewise many loiterers and it was difficult to conceive what they could find to do or what attraction such a place could present. Perhaps some were friends of those who really had work to do and were present as sympathetic spectators, but I mention their presence to show that all idlers who chose were admitted, and there was a still larger number of domestic animals present. A weird-looking goat peered at me from one corner, then there were several sheep and lambs, but more numerous than all were the cats. There must have been more than a hundred scavenger cats present. Cats are never molested in Egypt and these animals took no trouble to get out of the way; it was necessary to be careful so as not to tread on them. When they are tired of picking out food from among the garbage they go and lie down on one of the domed roofs and enjoy the warmth coming up from the baths which these roofs cover. Here the cats sleep till they are hungry again. Thus there are animals in numbers sufficient to make the place dangerously filthy, even if the household refuse and garbage brought in was quite clean in itself. Nor must it be thought that the scavengers especially select a cleaner sort of refuse to bring to the baths. On the contrary, it is simply household waste, green leaves, faded flowers, the peeling of vegetables, the offal of poultry or rabbits, broken pots and pans, rags and tatters, every sort of useless rubbish containing much moist and organic matter, all ready to ferment and add to the foulness of the surroundings.

In the domed roofs of the baths there are ventilators. From below there came puffs of steam through these apertures and the voices of the women and children bathing also ascended. Doubtless they thought they were cleaning themselves, but there were heaps of foul refuse piled up on much higher levels than the ventilators, and from these the dust descended through the apertures on to the bathers' naked skin just when the pores were open under the heat of the bath, and commendable as the practice of frequent ablution may be I felt that in Cairo it must have its risks. This particular hammam takes 186 cartloads of rubbish per month, and the stench and the flies engendered in this vast quantity of garbage and other refuse are appalling. Yet the hammam is in the very heart of the city and within a stone's throw of the headquarters of the army of occupation. From amid all this dirt I was able to look up at these headquarters and see British soldiers leaning out of the windows ready to breathe the dust the wind might bring them from the abominable accumulation of filth on which I stood. On leaving this hammam I went to several other similar but smaller establishments. The conditions were much the same. Evil-smelling refuse piled up in courts, dilapidated houses and roofs situated at the back of the baths and peopled by innumerable cats, together with some bigger animals, such as sheep, goats, and occasionally by geese. In one case there was a bakery with the rubbish on one side and a rag merchant's depôt and sorting place on the other side. Thus, from whichever side the wind might blow it would convey dust from a foul source on to both the moist dough and the baked loaves. The baker worked quite unconcernedly and evidently had no idea that his bread might easily be contaminated. Naturally no food should be exposed near places where refuse is stored and handled. As the scavengers' carts are emptied by hand into bags and their contents carried in small quantities at a time there is a great scattering of the dust, and this should not be allowed in narrow streets and thickly populated districts, particularly when food is exposed for sale close at hand.

The utilisation of household refuse for fuel thus gives rise to a serious and dangerous nuisance, and this in all parts of the town, since there were no less than 49 bath furnaces alight when I inquired into the matter, and there remained ten other bathing establishments that might also be utilised at any moment. On the other hand, if some portion of the refuse was not consumed by the bath furnaces then the difficulty caused by the accumulation of this rubbish just outside the city would be aggravated. Further, these furnaces not only warm the water for the baths but cook the beans in oil which constitute one of the staple articles of food for the people. These are brought in large earthenware jars and baked in the furnace. For cooking at home the only cheap fuel available are cakes of dried dung which make an evil-smelling smouldering fire. Obviously, therefore, one of the first necessities is some form of clean and cheap combustible material, such as, for instance, oil if no coal can be found near at hand. All foul rubbish could then be treated as manure and not employed as fuel save in some manner which is not antagonistic to public health.

There is also in Cairo a great danger that the dumping ground may be converted into sites for building purposes. On the other side of the Nile close to a main road passing near the Dookhi village there was a depression in the land and in this hollow water accumulated. Thus during several months of the year there was a pond of dirty stagnant water. Undoubtedly it would have been a good thing to fill up this hollow and level the ground, but of course this should be done with good clean wholesome earth or sand. The hollow has been used as a dumping-ground for household refuse Here the scavengers have brought thousands of cart-loads of all the rubbish they could collect. The hollow to the depth of six feet is now filled, the refuse flattened out and already children from the village play upon it as if it were a field, while herds of goats go there to see if they can scratch up and disinter some eatable garbage. This newly created field of filth is at the angle formed by the main road and a by-road leading to the village. Here at this angle two shanties have already been constructed and both for the sale of food. The shanty to the right of the illustration (Fig. 4) is a native restaurant.

FIG. 4.

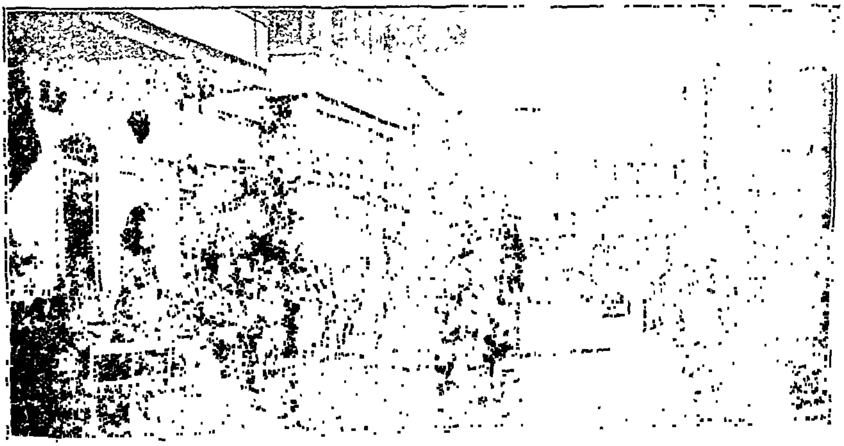


Shanty on the edge of the dumping ground, which was lately a pond. Note the proximity of a good dwelling house and the garbage heaped on the roof.

Outside, under the rough verandah, soup and sausages other cooked viands are exposed for sale. As if fearing tl would not be enough flies or sufficient dirt settling on food and coming from the neighbouring field made of refuse, some of the rubbish which the scavengers brought has been piled up on the roof of the shanty, as shown by the illustration. When I asked why this was done I was informed that the object was to make the roof thicker and therefore the inside of the hut would be
That this thickening consisted o
not trouble the minds of anyone
matter worse, the little hut immediately opposite is a small butcher's shop, and here meat is hung up to receive the flies and the dust from the vast area which has been converted into a scavengers' dust depôt. Doubtless the village, which was separated from the main road by the hollow, will now extend and houses will be built over the field of rubbish. The administration of the City of Cairo is not responsible for this abominable and dangerous proceeding, as the left bank of the Nile is within the Province of Gizeh.

The same evils, however, are likely to arise on the Cairo side. Indeed, I was informed that the Finance Department of the Egyptian Government had recently proposed to sell for building purposes some of the land that had been used for dumping the scavengers' refuse. The Road Sweeping Department, I understand, ventured to protest that such land was not fit for habitation. Thereupon the Finance Department replied, implying that it was an impertinence for street sweepers to interfere with State finance! Also, I heard that it had been decided to allow some enterprising individual to build working men's dwellings on the great dust depôts if he would first remove four metres deep of the rubbish. But where could he take this rubbish when removed? Obviously it is necessary to study and to bring forward some great scheme for the redemption and cultivation of absolutely
ish accumulated
The scavenger carts should be emptied into railway trucks and everything taken some 10 to 20 miles away from Cairo.

FIG. 5.



A low-lying street in Cairo flooded after a severe rain, owing to absence of sewers and drains.

In regard to collecting the refuse and to sweeping and keeping the streets of Cairo clean, the work is well organised and supervised; but, as already explained, not always effective because the service is undermanned. As might be expected, the Europeans are far and away the most untidy and the most difficult to deal with. No rule can be imposed on them. They will throw their refuse into the streets just after the latter have been cleaned. The scavenging department has erected large metallic receptacles in convenient places and calls upon the populations to put their
and not to throw it on the pavement
nsiderable
but many
of the Europeans defy the authorities and refuse to give themselves any trouble. The Copts—that is to say, the few native Egyptians who are Christians—imitate the

latter and are nearly as dirty, untidy, and difficult to keep in order as the Europeans themselves. They also display no regard for the injunctions issued and requests made by the scavenging department, but throw any garbage or offal into the street without hesitation.

There is great difficulty in dealing with all such minor offences. The native police hesitate to embroil themselves in proceedings against foreigners. If a European is justly prosecuted he will probably be condemned, but the native officer will do his best to avoid making an investigation and he does not clearly understand the European laws on evidence. Then the native police have no right of entry where Europeans dwell. Thus, for instance, if an Italian living in a second-floor flat throws filth into the street or shakes his carpet from the window at the wrong hour, the native police may persuade the Italian consul to consent to a reprimand being made. The sanitary authority could then enter the second floor flat if accompanied by the Italian consul. But the house may belong to a Greek, and then the sanitary authority cannot enter and pass through the lower part of the house so as to reach the second floor unless the Greek consul also gives his consent, and it is not likely that two consuls would hold the same opinion as to the importance of the offence committed. In such circumstances it is not surprising that many minor offences are passed over unnoticed if the culprit is a European protected by the Capitulations. But if there are many Europeans who are lax in the fulfilment of their duties of citizenship and are too careless to observe the rules and regulations drawn up for the common benefit of the entire community, they are quick enough to complain when anything happens that is personally inconvenient. Thus when it rains, and this may occur perhaps three times in the course of a year, the European will make a terrible fuss if there is a small puddle of water before his house. His virulent complaints will draw members of the over-worked staff away from quarters of the town where it is not a question of puddles but of regular floods that keep people prisoners in their houses.

This question of the floods is a very serious matter which fortunately will be solved by the drainage scheme. These floods occur in certain low-lying streets because there are no drains. Their extent is shown by the accompanying illustration (Fig. 5). The rain-water accumulates in these streets and there is no gradient for it to flow away. If left to itself the water would remain there until it had soaked into the ground or evaporated. Now powerful engines are sent and the water is pumped up into tank-carts and taken away. But before this can be done the water has mixed with such a filthy soil and surroundings that it gives off the foulest odours. The scavengers engaged in the work often turn sick, vomit, and lose the use of their voices for a few days. They are such sturdy men, however, that they are none the worse in the long run; at least, this was the statement made at the scavenging department. But however this may be, the fact that the men are sick confirms what I said, when dealing with the drainage scheme, as to the contaminated character of the soil on which Cairo stands. It shows also how much cleaning will be necessary before Cairo can become a salubrious city.

Not only will sewers have to be laid, but there are large districts covered by the vilest slum property that must be pulled down and rebuilt. Nowhere is the problem of the housing of the poor more acute than at Cairo. In regard to the drainage question I have shown that there is fair hope that this problem will be solved satisfactorily. Nor should there be any unsurmountable difficulty in obtaining an unlimited supply of efficiently filtered Nile water. The scavenging department is admirably organised; it only needs more money and more men. But when they have collected the refuse they have no efficient means to ensure its sterilisation. Some people imagine that it will be naturally disinfected by the action of the sun. There can be no more dangerous fallacy. Long before the sun has exercised its purifying action the wind has scattered dust far and wide. Also millions of flies have been bred and they convey from their native dust heap whatever germs it may contain and deposit them on the people or the food over which they crawl and disport themselves. A general scheme for the disposal of refuse will have to be formulated.

The housing problem in Cairo, the prevention of the adulteration and the contamination of food, the lack of power to impose protective measures against such diseases as small-pox, and other very important questions have also to be taken in hand. These are problems for the future, and I should like to have said more about them and also to have recalled in some detail the very excellent work that has been done to nip in the bud outbreaks of cholera and plague. But for the moment, at least, I have written enough about the sanitary problems of Egypt. It only remains for me to express my gratitude to the many persons who have assisted me in my task. At the Ministries of the Interior and of Public Works I found willing and courteous aid. The Khedival Medical Society made me the guest of the evening at its annual banquet. The Association of the European Press organised a special entertainment in my honour. To the European and the native press I am indebted for the very large publicity which they have given to my endeavours to promote the cause of hygiene in Egypt. The Egyptian Institute also held a special meeting at which I delivered an address on public health questions, and the leaders of the intellectual and scientific society of Cairo honoured me by their presence. Many persons in their individual capacity called on me and offered to help in my investigations. Altogether I was in the happy position of feeling that there was a real desire in Cairo to hear an independent report upon the sanitary matters of the city. I hope I have contributed to the stimulation of sanitary progress. Such, at least, has been the mission on which I was sent, as well as my only aim.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol.

THE various public bodies which are to assist in the government of the University of Bristol are electing their representatives. The Bristol city council has chosen for the court one life member (Alderman Elkins, chairman of the education committee) and ten others, and for the University Council five more. The General Medical Council was lately reminded by its President of two clauses in the Bristol University Bill, one empowering the University to examine for, and grant, Diplomas in Medicine, Surgery, and Midwifery; the other giving the Council of the University the right to elect a representative to be a member of the General Medical Council.

The Association of Alumni.

This association held its first annual meeting on June 9th at University College, Bristol. Professor Lloyd Morgan, the Vice-Chancellor of the University, who was in the chair, outlined the scope of the association, which would aim at bringing old friends together. It would, no doubt, correspond closely to convocation as far as the *personnel* of both is concerned; but the functions of the two would be different and would therefore not overlap. The Chancellor of the University, Mr. H. O. Wills, has kindly consented to be the honorary president, the acting president being Mr. G. Munro Smith, surgeon to the Royal Infirmary. The committee consists of the officers with two representatives from each of the four faculties. There will be an annual subscription of 4*s.*, life membership being conferred on subscribers of two guineas.

A Faculty of Commerce.

An address recently delivered before the Bristol Chamber of Commerce by Professor H. B. Lees Smith, who occupies the chair of economics at the new University, has been reprinted for general circulation. It is a most interesting and cogent plea for the foundation of a chair and a faculty of commerce. Professor Lees Smith, after alluding in general terms to the complexity of commercial enterprise under modern conditions, and the consequent need for special education of those entering upon such a career, gave a sketch of a curriculum which might be adopted by a faculty of commerce. The first year might include the study of a foreign language, economics, commercial geography, and public administration. Second- and third-year students might take up accountancy, commercial correspondence, and the technique of trade and commercial law. Owing to the diversity of commercial careers the curriculum would have to include a number of optional subjects. Under this heading he suggested a second foreign language, one or more scientific subjects, the history, theory, and organisation of banking, of foreign trade, and of transport, life and marine insurance, and the structure and organisation of some selected industry. The student might go through this course by means of evening lectures, while working in a business house, thus obviating any delay in the opening of his career. As a start Professor Lees Smith asked for a sum sufficient to endow a chair of commerce (which, he explained, would not be occupied by himself), with a salary of £500 or £600 a year.

The Late Dr. Hugh Montgomerie.

On June 2nd there was a large gathering at the West Cornwall Infirmary, Penzance, when the Lord Mayor of London unveiled a tablet, which had been placed over a bed endowed to the memory of the late Dr. Hugh Montgomerie, formerly honorary physician to the institution. The Lord Mayor said that Dr. Montgomerie was a bright example of many members of the medical profession who labour greatly among the poor without fee or reward.

An Action for Libel.

At the Hereford assizes on June 11th, before Mr. Justice Ridley, Dr. Harold Bertie Dickinson sued Mr. Stephen Beeson, a veterinary surgeon, for slander and libel. The evidence showed that acting upon information which had been supplied to him, the defendant accused the plaintiff of failing to notify to the medical officer of health a case of scarlet fever, and in his capacity as town councillor spoke of "this demon's carelessness," "diabolical conduct," also saying that "he ought to be drummed out of the town." The plaintiff stated that he did not notify the case earlier because he was not absolutely certain of his diagnosis. The jury returned a verdict in favour of Dr. Dickinson for £100, being £50 for the slander and £50 for the libel. The judge said that the defendant used very strong language and was undoubtedly in [illegible] previously been [illegible] Dickinson for [illegible] in his favour.

Longevity.

On June 9th, when the Prince and Princess of Wales were driving from Newquay (Cornwall) to the Royal Cornwall Show, which was being held at St. Columb, Their Royal Highnesses halted at St. Columb Minor to receive the respectful homage of Mr. James Carne, who is now in his 104th year. Mr. Carne enjoys good health and takes a daily walk.—Mrs. Margaret Arthurs of Rowde House, Bath, celebrated the 101st anniversary of her birthday on June 5th. Bath has another centenarian, Mrs. M. Henersley, who celebrated the 103rd anniversary of her birthday last October.

June 15th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Resignation of Professor Bennett May.

Professor Bennett May has resigned his appointment as professor of surgery, and in accepting his resignation the Council of the University expressed its regrets and gave to Professor May its best thanks "for his valuable and distinguished services to the Birmingham Medical School during a period of 33 years." It is quite certain that not only the Council but also his old colleagues and friends regret very much that the time has come when Professor May has felt that he must sever his connexion with the active work of the University. Those of the younger generation who have only been associated with Professor May since the foundation of the University scarcely understand the debt the Medical School owes to him, but his older colleagues, who know how he worked and sacrificed himself and was true to the best traditions of the school in the darker days when its fate wavered in the balance, appreciate to the full the work he did—work which helped so materially to place the school in the comparatively excellent position which it holds to day.

The New Nursing Home for the General Hospital.

In opening the new nursing home in connexion with the General Hospital, the Lord Mayor of Birmingham congratulated the board of management on the latest addition to the hospital, and said that "no similar institution in the kingdom could claim to be more complete or perfect than the General Hospital." The erection of the new home was necessitated by the continued increase in the numbers of the nursing staff. This has resulted, in great part, from the growth of the number of operations, which has increased from 1496 in 1898 to 3975 last year. The new home, which will cost about £8000, is conveniently situated; it contains 43 bedrooms, a class-room for instruction in cookery for the sick, it is thoroughly well equipped, and it forms a very satisfactory addition to the conveniences of the hospital.

The Hospital Sunday Fund.

At the recent annual meeting of the Hospital Sunday Fund the Lord Mayor was elected President for the coming year. [illegible] influence the subscriptions, and he appealed to those who favour the present conditions to do their utmost to sustain them. Dr. Jowett, however, was not satisfied that the problems suggested by the Bishop really had much influence at present upon the bulk of the people who formed the religious congregations, and he considered that if an endeavour were made to enlarge the general interest in hospital work increased support would be obtained. In accepting the appointment of President, the Lord Mayor said that those who believed that our medical relief agencies should be maintained on the present basis had not much to fear, for legislative changes which would throw the burden on the local communities would not be made till large majorities were in favour of the change.

The Bagnall Small-pox Hospital.

Suggestions are being made that the Bagnall Small-pox Hospital should be utilised as a sanatorium or convalescent home. If [illegible] siderable [illegible] costs £900 [illegible] have been no patients. On the other hand, if the hospital was not available and an epidemic occurred, the North Staffordshire district might be in a deplorable condition. The authorities will no doubt carefully consider all sides of the question before they deprive themselves of what might at any moment prove a vital necessity. And possibly a way may be found to make use of the hospital for some purpose which will not alter its general character and which will not prevent its use for its initial purpose should the necessity arise.

Lymphatism and Chloroform.

At an inquest held recently in Wolverhampton to inquire into the cause of death of a girl who was being operated upon in the Wolverhampton Hospital, it was explained that the patient, who was undergoing an operation upon a deformed foot, was apparently a healthy girl. According to the statement of the house surgeon, the patient began "to come round" before the operation was completed and then suddenly stopped breathing. Artificial respiration was resorted to and breathing recommenced. The operation was then proceeded with, and in a few minutes the breathing again stopped and all attempts to resuscitate the patient, [illegible] and the jury found a verdict in accordance with the medical evidence.

The Past and Present Sanitary Condition of Dudley.

In his annual report Dr. J. H. Wilkinson, the medical [illegible] when [illegible] and the state of affairs which prevails to-day. The death-rate varied from 32 to 36 per 1000; 150 people died from scarlet fever, 65 from cholera, and typhus fever was very prevalent. In certain districts there were about 6000 people with practically no water-supply and the general water-supply was very defective. Last year the general death-rate was 15·28 per 1000; the zymotic death-rate 1; there was no epidemic of zymotic disease, and there were very few houses which were not supplied with water. The contrast displays in a most effective way the improvement of public health which can be obtained by continued work on good lines.

Annual [illegible] of [illegible] Norton.

Dr. R. Green's annual [illegible] officer of health, upon the King's Norton and Northfield urban district shows how rapid the growth of the population has been in a comparatively short period, the total estimated population in 1907 being 75,508, and by the middle of 1908 it had increased to 78,608, whilst the total number of births over deaths was 1081. The immigration which has taken place has no doubt been largely due to the provision of trams and cheap houses, a combination of circumstances which has resulted in the migration of many people from the poorer parts of Birmingham, and which has made Dr. Green anxious to establish in the interest of his district some provision for the practical education of the mothers. He is anxious to keep down the infantile mortality rate, for, as he points out, though the births exceeded the deaths and the number of births was considerably greater in 1908 than in 1907, still the birth-rate (25·54 per 1000) was the lowest recorded, and the death-rate was 10·78 per 1000 as in 1907. Dr. Green notes that the male births greatly exceeded the female births, 1015 to 914, and that 76·1 per cent. of the children were vaccinated, that being 7 per cent. less than in 1907.

June 15th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Post-mortem Examinations in Workhouses.

SOME discussion, animated if not angry, took place at a meeting of the Chorlton guardians held on June 11th respecting a post-mortem examination made a few days before on a patient who had died in the Withington workhouse. The patient died, it is stated, from "pneumonia accelerated by delirium tremens," but after his death one of the medical officers suspected typhoid fever, and his colleague made a post-mortem examination. Before doing so he asked the consent of the patient's widow, "to determine whether typhoid was present or not, as it was a serious matter in a large workhouse." According to the widow and a sister they were told that unless they consented to a post-mortem examination there might be a difficulty in regard to the death certificate, and that the coroner would probably order one to be made. In answer to the coroner as to why he was named, the medical man in question said he did it "accidentally and in the interests of the institution," as he thought it ought to be known definitely whether typhoid fever had been present or not, and, while regretting his action, disclaimed the intention the coroner had suggested of an attempt to frighten the widow. The coroner said that the proceeding was "not merely indiscreet but most improper; the case was one which never would have come before him," and he required an assurance that such a thing would not occur again. It is a serious thing to question any of the dicta of a constitutional authority, but it may be conceived possible that the coroner, usually so judicial, may have been unduly angry at something which the medical man did not intend. It is curious that no mention was made at the inquest of the question of typhoid fever, for in that case to the verdict, "Death from natural causes," the jury would not have added their view that "the doctor should be censured." This might be called a rider to the verdict, to which the coroner seems to have offered no objection. At a meeting of the Chorlton guardians on June 11th the matter led to a long discussion, one or two of the guardians saying that intimidation had been used, that a record ought to be kept of such cases, and that the medical men held this examination in their own interest. Another guardian, a woman, said that far too many post-mortem examinations were made at Withington, and no one benefited by this one but the medical man who made it. "The hospital should not be a practising ground for young doctors." The chairman protested against such charges being made. Another guardian said that they were absolutely without foundation; permission was given prior to the name of the coroner being mentioned but there were objections, and the medical man explained that if the case went to the coroner there would probably be an examination. Anyone who has seen much of workhouse practice will be prepared for some discrepancy in the statements of relatives at different times, but it is a pity to see guardians, presumably of some education, using such wild words of condemnation as were indulged in by some of the members of the board. It is not likely that a medical man, even if young, would undertake something so unpleasant as a post-mortem examination unless he believed that some increase of knowledge might result which would probably benefit his fellow men.

Whisky and Saffron in Measles.

At an inquest held yesterday by the Manchester coroner, Mr. Gibson, on the death of a child from pneumonia during measles, the mother said that when she found the child had measles she gave it saffron and whisky. This is a common proceeding in a certain stratum of the community, and Mr. Gibson told the jury that 99 out of 100 parents gave saffron and whisky and such like things when children had measles. This is a remarkable testimony to the quality of the compulsory education bestowed on the children of the nation for more than 30 years. The coroner expressed the hope that sooner or later people would be educated up to the fact that measles is a particularly fatal disease and that they would pay more attention to their children and call in a medical man when they have this disease. Is this a vain hope, or may we look in the future for more common sense being infused into the education of the coming generation?

Electrical Dangers.

The dangers of our present arrangements for making use of electricity were alluded to quite recently, but may again be illustrated by the occurrence in Manchester of a serious explosion early yesterday morning. Happily it took place about 2.30 A.M., and though sufficiently disastrous, there was no loss of life. A policeman saw a cloud of black smoke coming from the main entrance of the Victoria Arcade. Before he could get there a heavy report took place, followed by a blinding flash and a sheet of flame which was said to be 20 feet high. Simultaneously, the huge revolving iron shutters which bar the entrance to the Arcade, and which were closed, were blown out bodily, and a large portion of them was carried right across the street. Hundreds of windows were wrecked, offices were dismantled, solid concrete from the pavement was hurled in every direction, and a brick broke through a plate-glass window on the opposite side of the road. The whole of the front of a bank was forced out, the floor torn up, and books scattered all over the place. Other premises were also much injured, the windows wrecked, and fittings badly damaged. Inside the Arcade hundreds of panes of the lofty glass roof were shattered. The explosion also wrecked the gas and water mains, and at the entrance "a hole was made fully six yards deep, 14 yards long, and five yards wide." The damage, which cannot as yet be accurately determined, is estimated at £5000. If the explosion had occurred in the day-time the fatalities would probably have been numerous. It was said that the fault occurred at a point where the service wires laid into the Arcade are joined on to the [illegible]ng St. Mary's Gate under the foot-path. [illegible] which was the primary cause of the disaster, was old, dating from 1896. These old joinings are being rapidly replaced by improved ones, but unfortunately not in time to prevent accident. The first indications of mischief were almost like the precursors of an earthquake. At 1.45 A.M. the recording instruments pointed to a slight disturbance near Deansgate. The "standby" men were sent out but could find nothing wrong. About 2 A.M. complaints were made from the Victoria Hotel and several printing offices, but the standby men sent out again could still find nothing wrong. This little story shows what a terrible power we are using and the absolute need there is for keeping it under control. We hear far too much of fused wires.

June 16th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool School of Tropical Medicine; the Expeditions and their Work; Complimentary Dinner.

WITHIN the last few months there have arrived in Liverpool a number of scientific gentlemen who had been sent out, under various expeditions, to the tropics by the Liverpool School of Tropical Medicine. Their successful researches and their return were made the occasion on June 14th of an interesting function at the University club, where the gentlemen in question, 12 in number, were entertained to dinner by Sir Alfred Jones, the chairman of the school. The principal guests were Professor Sir Rubert Boyce, Professor Ronald Ross, C.B., Professor J. L. Todd, Dr. J. O. W. Barratt, Dr. Anton Breinl, Dr. A. H. Hanley, C.M.G., Dr. Allan Kinghorn, Dr. H. Wolferstan Thomas, Dr. W. Prout, C.M.G., Dr. Warrington Yorke, Mr. R. E. Montgomery, and Mr. R. Newstead. A number of prominent citizens were also invited. Before proposing the toast of "The Expeditions" the chairman asked the company to honour the memory of two members of the school—Dr. Walter Myers and Dr. J. Everett Dutton—who had lost their lives on expeditions. The toast was honoured in silence, all present rising. Sir Alfred Jones, in proposing "The Expeditions of the School," said that Liverpool had done a great deal in setting an example to the world of what might be done to benefit the tropics. That gathering was representative not only of British students but of students from all countries, and especially from Canada. In Africa the death-rate had been appreciably reduced by the efforts of the various expeditions. It was a great satisfaction that other countries had worked together with them, including America, France, Germany, and Sweden. Mr. Newstead and Professor Todd replied to the toast. The toast of "The Study of Tropical Medicine" was acknowledged by Dr. J. W. W. Stephens (Walter Myers lecturer in the school). Sir Edward Evans, in proposing "The Chairman," said that one of the greatest causes for the benefit of mankind had been brought to a successful issue. This had been due very much to the energy and force exhibited on all occasions by their host. Sir Rubert Boyce testified to the great interest which Sir Alfred Jones took in regard to tropical medicine. Professor Ross also spoke to the toast. The chairman, in responding, remarked that Liverpool ought to do more for the Tropical School. He had written to the bishop of the diocese, suggesting that they ought to have a "Tropical School of Medicine Sunday," just as they had a Hospital Sunday collection.

William Mitchell Banks Memorial Lecture.

The date of the William Mitchell Banks memorial lecture has been fixed by the council of the University of Liverpool for August 4th, at 4 P.M., in the surgical theatre of the medical school. The date is a little unfortunate for obtaining a large audience owing to the holiday season, but it had to be so arranged to meet the convenience of the lecturer, Dr. Harvey Cushing of Baltimore. Dr. Cushing is associate professor of surgery at the Johns Hopkins University, Baltimore, and from his distinguished surgical reputation it is anticipated that there will be many in Liverpool desirous of hearing his address.

Liverpool Hospitals and Civic Grants.

The Liverpool finance committee has recommended the city council to authorise the Parliamentary committee to include in its next application to Parliament power to contribute a sum not exceeding £5000 towards the erection of the new building for the out-patient department of the Royal Infirmary, subject to the Infirmary committee raising the balance of the money necessary (probably £45,000) to complete the building. Towards the erection of the out-patient department of the Royal Southern Hospital the finance committee recommended a contribution by the corporation of £4000.

June 15th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Death of Mr. John Henry Williams, M.R.C.S. Eng., L.S.A.

THROUGH the death on May 27th, from pneumonia, of Mr. John Henry Williams, the medical profession in the Swansea district have lost a most agreeable and popular colleague. He was born in North Wales in 1858 and received his medical education at the London Hospital, subsequently p[illegible] About 14 years [illegible] a fair share of [illegible] a great interes[illegible] officer of [illegible] byther, Carmarthenshire. [illegible] life of his adopted town, he [illegible] cil of Aberavon in 1896 and was mayor in 1901. As a member of the Swansea port sanitary authority, whose area of administration extends to Port Talbot and Aberavon, he rendered conspicuous service. He was on the commission of the peace both for the county of Glamorgan and for the borough of Aberavon. Mr. Williams had only been married about eight years, and leaves a widow and two children to mourn their loss.

Cardiff Asylum.

The great increase in the population of the county of Glamorgan, which in the ten years ending 1901 was nearly 180,000, made it necessary for the county council to insist upon the Cardiff corporation providing separate accommodation apart from the Bridgend Asylum for insane persons who are chargeable to the Cardiff Union. The institution erected by the corporation for the purpose is situated just outside the boundary of the borough and has accommodation for 750 patients, with administrative facilities for 1250. It has been occupied a little more than a year, and already on the male side the available accommodation barely suffices for the needs of the town, although on the female side there are nearly 100 vacant beds. In these circumstances the asylum committee is endeavouring to prevail upon the board of guardians to provide accommodation in the union buildings for certain imbecile and epileptic patients, who it is considered might be cared for in a less costly manner than is found to be possible at the asylum. The weekly cost per patient at the asylum during the first year of its occupancy was 13*s.* 5*d.*, but this sum has now been reduced to 13*s.* 1½*d.*

The National Library of Wales.

In the distribution of the national institutions the Welsh Museum is to be located in Cardiff and the Welsh Library in Aberystwith. At a meeting of the court of governors of the National Library held on May 29th, and presided over by Sir John Williams, it was reported that six plans had been received in competition for the proposed buildings which it is intended to erect at a cost of between £70,000 and £80,000. In the plans selected [illegible] in the form of a quadrangle, the [illegible] in the centre at the front, fla[illegible] exhibition hall and on the other by the great library hall. The quadrangle is completed by the book block which is arranged to hold 332,000 volumes. In the library hall an additional 100,000 books can be arranged within sight of the readers, while the exhibition hall provides space for the exhibition of rare and interesting books, manuscripts, &c. The administrative block includes council and committee rooms, with rooms for the librarian and the president.

Crime in South Wales and Monmouthshire.

For many years past the northern, central, and western parts of Wales have been remarkable for the absence of crime among the inhabitants. In the colliery districts of South Wales and of Monmouthshire the very reverse has been the case, and there is rarely an assize held at which one or more revolting crimes have not to be investigated. At the Monmouth assizes on June 7th a young collier, 24 years of age, was sentenced to death for the murder of a farm woman who was nearly 60 years old. The evidence showed that he first of all shot her in the face, he then outraged her, and finally cut her throat. In spite of these injuries the woman was able to walk to a neighbouring farm, whence she was taken to a hospital, and she lived until May 5th, the attack having been made upon her on Feb. 20th. The evidence of the county analyst was of interest from the point of view of medical jurisprudence, for he stated that he had discovered on the man's clothing as well as on that of the woman certain fibres which had the same characteristic appearances, and that fibres of a similar kind were subsequently found in the composition of the mat upon which the woman declared she had been thrown by her assailant.

The Aberdare Medical Officer of Health.

The action of the Aberdare urban district council in attempting to place upon its medical officer of health duties which should properly be performed either by a veterinary surgeon or by an analyst has already been discussed in THE LANCET.[1] It will be remembered that the council, in re-appointing Dr. M. J. Rees for a further term of one year, sought to impose a condition that he should examine the milk supplied to the district for the purpose of ascertaining if it had a tuberculous origin. Dr. Rees very properly declined to accept re-appointment on these terms, and upon the matter being referred to the Local Government Board his action was upheld, and the Board recommended that he should be appointed on the same terms as formerly except that he should not come up for re-election year after year. It is gratifying to find that the council has now by a very arge majority carried out this suggestion.

June 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Resignation of Professor John Cleland.

AT a meeting of the Court of the University of Glasgow held last week a letter was read from Professor John Cleland intimating his resignation of the Chair of Anatomy which he has held since the year 1877. Throughout this long period he has been a great personality in the University, and much respected and admired by the many generations of students who have passed through his hands. Among the more important of his writings are his thesis on the structure and mechanism of the gubernaculum testis, and his papers on the development of the skull and cranial variations, which appeared in the Philosophical Transactions of the Royal Society of London in 1862 and 1870. Recently Dr. Cleland collected in a volume, entitled "Memoirs and Memoranda in Anatomy," many of his contributions to the literature of the subject during the last 40 years. In his text-book, published in association with Dr. J. Yule Mackay in 1896, he included much of his own original work. Another volume of his, entitled "Evolution, Expression and Sensation," includes his speculations on the great problems of thought as they present themselves to the naturalist. As a monument in the University Dr. Cleland leaves behind him the splendid anatomical museum which has been built up under his constant supervision. The University owes him a deep debt of gratitude for the development of his department and also for procuring for it buildings commensurate with its importance.

Sidlaw Sanatorium.

At a meeting on June 8th the last word was said as regards the cancelling of the arrangements between the directors of the Sidlaw Sanatorium and the Dundee town council providing for the transference of the institution to the latter body. At the commencement of negotiations the donors and annual subscribers to the institution passed a resolution in favour of the agreement which was adjusted between parties, and which, besides handing over the buildings, established a new body of trustees, in whose hands the endowments should remain. As a result of the opposition to the movement the Dundee town council reversed its decision, and asked that the donors and subscribers to the sanatorium should consent to render the agreement void. As stated at a meeting on June 8th they agreed to this, but in addition they altered the constitution so that power might be possessed, subject to the approval of the Secretary for Scotland, for handing over the buildings and equipment at a future time to the corporation, and establishing, when and if that time comes, the new body of trustees.

Insanitary Condition of Lewis.

A special meeting of the Lewis district committee was held on June 9th. The meeting considered the motion of the chairman, Provost Anderson, to the effect that—

> In view of the large number of insanitary houses in Lewis, caused principally through cottars having been allowed to erect houses in clusters about the dwelling houses and byres of the crofters; and, further, in view of the fact that the cottars made no contribution towards the cost of education, poor relief, roads, public health, and [illegible] nes do not appear on the valuation roll [illegible] pro- [illegible] the [illegible] the [illegible] d to be acquired from the respective townships, moors, grazings, or skinned lands, or on other suitable lands; and, further, that the committee respectfully ask His Majesty's Government to help in the matter by giving grants or loans for the building of suitable dwelling houses for such cottars as may be so settled, and also for reclaiming portions of the skinned or other lands referred to, and that copies of this resolution be forwarded to Major Matheson, the Secretary for Scotland, and the Lord Advocate.

In submitting the motion, Provost Anderson referred to the unfortunate state of matters in Lewis as regards public health. This was entirely due to the number of houses crowded together on crofts. The only practical remedy was to have these houses removed and fresh sites obtained for new houses. He believed that the Government would help in the matter. The committee had been pressing the matter for 15 years, and he thought that the time had come when the committee must strenuously press the matter upon the proprietor and the Government. The motion was seconded and carried. The clerk was instructed in forwarding the motion to the proprietor to state that the committee would be pleased to confer with him if desired.

Aberdeen University Court: Resignation of Professor Ogston and Dr. Angus Fraser.

The Aberdeen University Court met on June 8th. The letter from Professor Alexander Ogston resigning the chair of surgery in the University was submitted. Professor Matthew Hay, who presided, moved that they enter in their minutes an expression of their appreciation of the value of the eminent services which Professor Ogston had rendered to the University as a teacher and investigator of the highest order and of their regret at his retirement. Professor Hay also referred to the loss in the medical teaching staff occasioned by the retirement of Dr. Angus Fraser from the senior physicianship at the Royal Infirmary. The reconstruction and reorganisation of the infirmary was largely due to his initiative. There was not one of their many medical graduates in all parts of the world who would not feel that the University had for them lost much of its glamour in the removal from its medical school of the names of Hamilton, Ogston, and Angus Fraser.

June 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Presentation to the Governor of the Apothecaries' Hall, Dublin.

THE members of the Apothecaries' Hall, which has the distinction of having been founded by the Irish Parliament in 1791, met on the evening of June 11th for the purpose of presenting a piece of plate to Dr. G. R. Seymour Stritch, J.P., their Governor, on the occasion of his marriage. Colonel Adye-Curran, M.D. Dub., F.R.C.S. Irel., occupied the chair, and amongst the other members present were Mr. C. J. Powell, Deputy Governor, Dr. E. Magennis, J.P., Mr. O'Connell Delahoyde, Mr. J. T. D. Crinion, Mr. W. F. Delany, Mr. J. Evans, Dr. E. F. Hanrahan, Mr. J. A. Whelan, Dr. J. C. McWalter, and Mr. H. W. Mason. Colonel Adye-Curran remarked that it was a unique circumstance to have a Governor of the Apothecaries' Hall married during his year of office, although they had an unbroken series of men occupying that honoured post for 150 years. He begged Dr. Stritch to accept of the service of plate, not for its intrinsic value, but as a proof of the high esteem in which he was held by his colleagues for his genuine good fellowship, his high scientific attainments, his invariably courteous demeanour, and his uniformly amiable disposition. He trusted that both himself and Mrs. Stritch would long be spared to brighten the lives of the directors by their friendship. Mr. Powell, Dr. Magennis, and other members of the board also felicitated Dr. Stritch on his marriage and expressed their delight at being able to give him some mark of their appreciation. Dr. Stritch, in reply, thanked his colleagues for their generous gift and stated that it was the proudest moment of his life and the consummation of all his ambition. He deemed it a very distinguished honour to have been elected President of that ancient corporation, the oldest licensing board in Ireland, but the generous gift of his friends had almost overwhelmed him with emotion and pride. All his life he had been averse from receiving testimonials, but this gift was so spontaneous that it would be cherished by him and his descendants as their most precious heirloom. Their presentation would stimulate him to renewed efforts in the cause of medical education in Ireland to the end of his life.

Cork Medical and Surgical Society.

The annual general meeting of this society was held on May 26th. The principal business was the election of officers for the session 1909-10. The following were the results:—Dr. D. T. Barry, professor of physiology, Queen's College, Cork, was elected President, and Dr. J. Booth Vice-President. Dr. Charles B. Pearson was elected honorary treasurer and Mr. Edward Murphy honorary librarian. Mr. James T. O'Connor was elected secretary. The council is constituted as follows: Dr. C. Y. Pearson, Mr. P. G. Lee, Dr. T. G. Atkins, Mr. Moore, Dr. M. Cagney, Dr. J. Cotter, and Dr. Lucy E. Smith.

The Belfast Corporation and the Health Commission.

At a special meeting of the city council of Belfast held on June 9th, on the motion of the Earl of Shaftesbury, it was decided by 17 votes to 9 to instruct the finance committee to pay the Local Government Board the sum demanded by it (£600) in respect of the cost of the Health Commission for the expenses of the three commissioners outside Ireland, Colonel Harding (chairman), Dr. L. W. D. Mair (London), and Dr. A. K. Chalmers (Glasgow).

The Belfast Board of Guardians.

At the annual meeting of the Belfast board of guardians held on June 9th Mr. J. S. Bryars was re-elected chairman of the board for the ensuing year. One of the older members of the board, in seconding Mr. Bryars's election, said no better chairman had occupied the position during his long period of membership.

Double Tenancies in Belfast.

There is nothing worse in Belfast from a public health point of view than the continued existence of double tenancies. The evil, though condemned by leading citizens and judges from the bench, and though well known to the public health committee, has existed for years, and nothing was really done to cope with it until the authorities were stung by the report of the Public Health Commission, which said:—

> This double tenancy was not alleged to be necessary even on the ground of poverty of the tenants, yet it has been tolerated for years, [illegible] and to the [illegible] provided [illegible] be closed [illegible] uld spare [illegible] ousing in [illegible]

The public health committee then made a sort of attempt to grapple with the evil. However, at a meeting of the committee held on June 10th it was decided to rescind a previous resolution as to serving of notices to provide the necessary sanitary accommodation, the excuse being put forward that the landlords of such abominable property prefer to give up possession of the dwellings rather than comply with the [illegible] impossible [illegible] One of the [illegible] 11th, in a leading article comments as follows on this action of the public health committee of Belfast:—

> It is the sheerest nonsense to pretend that there is not sufficient [illegible]
>
> efficiently, and appoint men who would see that hundreds of citizens were not allowed to live under conditions that would be a disgrace even to Darkest Africa.

June 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Operative Treatment of Leukoplakia of the Tongue.

AT a meeting of the Société de l'Internat des Hôpitaux de Paris held on May 27th M. Fourmestraux described the case of a patient suffering from extensive leukoplakia of the tongue and treated by a slight modification of Morestin's operation—namely, complete detachment of the mucous membrane of the tongue. He called attention to the unsatisfactory nature of the results obtained in the great majority of cases by medicinal and specific treatment. The use of the bistoury for this purpose required general anæsthesia and the same precautions as in removal of cancer of the tongue, including Rose's position, short anæsthesia, and fixation of the tongue. Local or regional anæsthesia was only indicated in circumscribed leukoplakia. As in operations for cancer of the tongue, the great danger consisted in the supervention of deglutition broncho-pneumonia. Frequent washing of the mouth and as short as possible a period of confinement to bed were essential.

Sarcoma of the Scapula.

At a meeting of the Surgical Society held on June 2nd M. Mauclaire described a case communicated to him by M. Le Fort, the patient being a man, 32 years of age, who suffered from a sarcomatous growth of the scapula as large as the fist and of seven months' duration. After removal of the growth M. Le Fort endeavoured to form a humero-clavicular articulation by suturing the bones together. Primary union occurred. The sarcoma was of the nature of myeloplaxoma. Two months afterwards the movements of the limb were tolerably free, but four months later there was a recurrence of the disease which necessitated disarticulation of the clavicle for the complete removal of the growth. At the time of the operation a hissing sound was heard on two occasions, showing that air had been admitted into the subclavian vein. This had no immediate consequence, but three-quarters of an hour after the operation hemiplegia of the left side made its appearance, lasting, however, only a few days. Some months later the patient succumbed to a fresh extension of the disease, which had invaded the lung. M. Le Fort did not think that the hemiplegia was due to the entrance of air into the vein. He referred to the satisfactory action of the new articulation, which formed a kind of pseudarthrosis. M. Mauclaire said that in his opinion it would be useful for a patient in such circumstances to wear some kind of mechanical support for the limb, because pain might arise from dragging on the nerves and retracted vessels.

Chronic Inflammatory Lesions Produced by a New Mycelium.

At the same meeting of the Surgical Society M. Auvray gave an interesting description of a chronic inflammatory lesion which closely resembled tuberculosis but was due to the hemispora stellata, a fungus recently described by Villemin. The case recorded by M. Auvray was the second of its kind and has been very carefully examined. The patient was a man suffering from an inflammatory swelling in the region beneath the angle of the jaw; it was quite superficial but of so chronic a character as to have the appearance of a tuberculous lesion. After removal M. Auvray had it examined histologically and also had cultures made. Structurally it was very similar to tuberculous tissue, having giant cells surrounded by epithelioid cells. Cultivations yielded no evidence of tuberculosis but only very pure cultures of hemispora stellata. The lesions due to this fungus were therefore both clinically and histologically very similar to those of tuberculosis.

Bread-making by Machinery.

At the Academy of Medicine on June 1st M. Railliet said that the hand-kneading of dough by bakers was not without possibilities of danger for the consumers of the bread. In contrast with this primitive system he recommended the use of the dough-kneading machine and mentioned the satisfactory trials of it which had been made by the association (*syndicat*) of Paris bakers under the supervision of Professor Ringelmann and Professor Lindet. M. Railliet declared that the machine-made bread was not only in quality and appearance quite as good as the hand-made but was also cheaper. The machine fulfilled every hygienic requirement and saved the working bakers from the excessive fatigue which was so favourable to the development of tuberculosis. On these grounds machine-made bread presented obvious advantages from the consumer's point of view.

Mutual Aid Associations and Medical Practice.

The Ministry of Labour and National Thrift (*Ministère du Travail et de la Prévoyance Sociale*) has published a report on the operations of mutual aid societies during the year 1904. The section on medical and pharmaceutical expenses is very interesting. In that year the disbursements of the free societies (*sociétés libres*) included the payment of 1,600,000 francs for medical fees by 1505 societies and 792,457 francs for pharmaceutical charges by 1466 societies, the number of patients being 99,550. Another group of societies (*sociétés approuvées*) had in the same year 446,392 patients on account of whom 4,064,151 francs were paid to the medical practitioners and 4,765,166 francs to the pharmacists. In the *sociétés approuvées* each patient therefore cost 9 francs for medical advice and 10 francs 70 centimes for medicine, whilst in the *sociétés libres* the analogous charges were about 6 francs for medical advice and 8 francs for medicine. In the *sociétés approuvées* the 446,392 patients were ill for an aggregate of 7,187,441 days, and in the *sociétés libres* the 99,550 patients were ill for an aggregate of 1,456,935 days, or a general average of 14 days' illness per patient. For his attendance during these 14 days the medical practitioner received 6 francs from the *sociétés libres* and 9 francs from the *sociétés approuvées*.

Treatment of Cancer.

At a meeting of the Academy of Medicine held on May 25th M. Tuffier gave an account of his treatment of cancer by various physical methods recommended of late years, including x rays, high-frequency currents, radium, and superheated air. *In his opinion, none of these methods* of treatment were ever followed by genuine recoveries, but the observation of the manner in which they individually acted was an interesting study. The x rays had a specific influence on the cancer cells, but not on the other anatomical elements; this influence on the cancer cells was, however, limited to a depth of less than two millimetres from the surface. Radium also had a selective power of attacking cancer cells, and in course of time this effect might extend to a depth of two centimetres from the surface. High-frequency currents had no selective action on the cancer cells; whatever slight effect they produced was distributed over the tissues generally. A jet of air heated to 300° or 400° C. acted not unlike a high-frequency current, only rather more capriciously.

Medical Attendance on Pauper Patients.

The medical practitioners of the town of Chalon-sur-Saone, being dissatisfied with the system under which medical advice is given free of charge both in that town and in the entire department, have sent an ultimatum to the municipality and have resolved to cease giving attendance under the present system if the modification proposed by them is not adopted by June 30th. They request that all the medical men practising (*patentés*) in Chalon and willing to accept the position shall be placed on the list of medical attendants of poor persons. Patients will be seen at the relief office (*bureau de bienfaisance*) on Mondays and Wednesdays at 10 A.M. by the medical men on the list, each of them serving in his turn for a month at a time with a remuneration of 5 francs for each attendance. Patients requiring to be visited at home may select their medical attendants, who will receive 1 franc for each visit.

June 12th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Food and Clothes for Indigent School Children.

Dr. F. Elsrismann, town councillor and head of the sanitary department of the town of Zürich, has just published a lengthy report on the gratuitous supply of food and clothes to school children in Zürich. For many years poor school children in Switzerland have received food (either breakfast or lunch) supplied partly from private sources and partly from local district authorities at the public expense. Of late years the expenditure to be met by the ratepayers has been rapidly increasing. Already, in 1894, Dr. A. Huber reported that out of a total of 475,000 school children attending the primary schools and aged from 6 to 11 years, 25,000 were supplied with food and 30,000 with clothes. Nearly one-third (28 per cent.) of all the public schools in Switzerland had introduced this system. The children in question either lived more than half an hour's journey from the school-house or were underfed at home. In Zürich the system is as follows. A minority of the children, some 700, receive milk diet, the majority are served with a simple soup meal, sometimes with the addition of meat, for such reasons as the poverty of the parents, the poor state of nutrition of t children, absence of the parents from home at midday, th large number of the family, and the unemployment or illne of the parents. The number of children thus provided for i Zürich, which has a population of 180,000, has risen fro 256 in 1894 to 2251 in 1902-03, and to 3334 in 1907-08. Th annual outlay has increased from 7200 francs (£88) in 19 to 48,367 francs (nearly £2000) in 1907-08. During the la year over £2400 were spent for this purpose. The expense each meal varies from 1½*d.* to 2½*d.* An increasing numb of children were furnished with necessary articles of clothin (785 in 1907-08), and the expenses reached a sum of 540 francs, or about £216. The great amount that is done f the physical welfare of school-children in Zürich is evidence by the further facts that in 1908-09 a sum of £2160 was spe for [illegible] classes of supervision and recreatio als [illegible] nd a further sum of £1600 to provid 1000 children with a three weeks' stay in the Alps.

Infantile Mortality in Switzerland.

The Federal Statistical Office at Berne has published th following details on the mortality of children under the ag of one year. Since 1876 the statistics show that for ever five years the mortality per 1000 births has undergone a continual decrease from 188 to 134, the last-mentioned figure being for the period 1901-05. This decrease has continue in 1906 and 1907, when the deaths were respectively 126 an 121 per 1000 births. The different cantons vary considerably in this respect, some having a very low infantile mortality, such as Unterwalden with 79 deaths per 1000 births In other cantons the corresponding figures are exceptionall high—namely, 157 in Valais, 187 in Fribourg, and 188 i Tessin; whereas Vaud and Neuchâtel with 144, Zürich wit 124, and Berne with 121 deaths per 1000 births keep about the average.

Zurich, June 12th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Darwin Centenary.

THE catholicity of science will have fresh illustratio next week in honouring the hundredth anniversary of th birthday of Charles Darwin. Every civilised nation will join i the *festa*—none more cordially than the Italian. For month past her press, medical and lay, scientific and political metropolitan and provincial, has either devoted specia articles to the theme or given extended reports of *éloge* of the master from academic chairs. Among these latter one of the best inspired was that of the professor o the history of the natural sciences in the Roman University, Dr. Mario Cermenati, summarised about a yea ago in THE LANCET; while among the independent tributes offered by individual students to "the immortal memory" none will be read with warmer appreciation than the "Profilo," as he modestly calls it, of Dr. Alberto Alberti.[1] A brighter biography of the author of the "Origin of Species" it would be difficult to find in the same compass, and the estimate of the man and his work will be seen to have the impartiality due to a detachment which, according to Madame de Staël, makes the "judgment of foreigners that of a contemporaneous posterity." One merit it will be found to possess—a merit, I regret to say, not in all cases characteristic of Italian treatment of the same theme—abstention from anti-religious or anti-Christian polemics. As already pointed out in these columns, many tributes to Darwin, particularly in Italy, have been marred by an aggressive attitude towards the "creeds," national or nonconformist, an attitude with which Darwin himself was not in sympathy and would certainly have been the last to countenance or to encourage.

At the Vatican.

The edile, under the inspiration of Pius X., has been busy in the apostolic palace recasting the accommodation of the *personnel*, high and low, to the great improvement of its conditions, sanitary and other. Hitherto the said *personnel* has been scattered up and down and right and left in the vast tenement, or congeries of tenements, but now they will find shelter in the "grandioso edifizio" which is just completed and only waiting to be occupied. Any impatience on the part of the prospective lodgers to "enter into residence" has, however, been met by a wise veto emanating from His Holiness, to wit, that they must find temporary accommodation elsewhere until the close of the summer months, by which time the brand-new "edifizio" will be thoroughly dried. So all the *personnel* will have to clear out with the exception of the Cardinal Vicar (Merry del Val), Cardinal Gasparri, the Monsignori Bisleti, Misciatelli, and Pifferi, and the secretaries and private chaplains. Another wholesome provision will be the transference of the Vatican Pharmacy from the Cortile of San Damaso to the new edifice. The Vatican will thus be spared the unsightly spectacle, not to say the positive inconvenience, of men, women, and children armed with medicine bottles or baskets coming in from the Borgo or adjacent quarters and meeting the cardinals, archbishops, and other dignitaries face to face on their way to or from the presence of the Holy Father. The Pharmacy, I may add, sharing the privileges accorded to the Holy See under the "law of the guarantees"—a law framed by the Italian Government and partially acquiesced in by the Vatican—can provide medicines, surgical appliances, and such like articles at a cheaper rate than the rival establishments outside, as it pays no octroi duty, nor "business tax," nor house-rent, and gets its lighting and heating gratis. It is much resorted to accordingly by more than the "faithful," and has been found a convenient and freely utilised mode of admitting to this or that official the importunate client, or the needy petitioner, or even the decently attired mendicant. So that the imminent changes in the accommodation of the Apostolic community will not only make for improved sanitation, for economy of time, and for acceleration of business, but will also conduce to the amenities of a quarter which has long been, and is destined long to continue, the most largely and multifariously frequented in Rome.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Hot Weather and the Schools.

IN Austria, where compulsory education is responsible for [illegible] children between six and 14 [illegible] daily, the intense heat in [illegible] often caused much discom[illegible] had to be in school from 2 to 4 P.M. Several times the school boards have attempted to introduce a system of continuous attendance for five hours from 8 A.M. to 1 P.M., thereby saving the children and the teachers the necessity of coming twice a day to school. The Ministry of Education has, however, this year tried to make the children come twice a day to school, in spite of the "Hitzeferien" (hot-weather holidays), as these idle [illegible] termed. Parents naturally made [illegible] and conflicts resulted. Finally [illegible] the school attendance to four hours before noon and leaving out the afternoon lessons was agreed to if the temperature at 10 A.M. reaches 20° C. (77° F.). At the same time it has been decided to bring the next school term to an end on July 1st and to have the holidays in July and August, which are the hottest months with us, and not as at present from the middle of July to the middle of September. The changes are due to the reports of several school medical officers, who as yet are too few in number to compel attention, but whose reports are already much appreciated.

The Jubilee Fund "for the Children."

At the recent jubilee of the Emperor a fund was collected bearing the title "Für das Kind" (for the children), as the Emperor wished that the money intended to be laid out on the jubilee celebrations should be devoted to charitable purposes, notably for the benefit of children. The fund has now been handed over to the organisation committee, which consists of 56 members, mostly presidents of various charitable institutions, medical men, and five ladies. The objects of the fund are: (1) to found model institutions for the protection of children; (2) to make grants in aid of already existing institutions of this kind; and (3) to arouse among the general population an interest in measures intended for the protection of children. All endeavours to promote the mental and bodily development of the juvenile portion of the population come within the scope of the fund, which it is inte[illegible]
so t[illegible]
for[illegible]
mir[illegible]
Fur[illegible]
do[illegible]

Professional Secrecy and Sources of Public Danger.

In a case heard recently in a court of law the familiar question of professional secrecy and the duty of the medical practitioner towards the public and the patient were well illustrated, and much comment in medical circles has been caused by the legal decision. A medical man who was treating a female patie[illegible] warned her that she m[illegible] owing to her position [illegible] neglected his cautions and when he saw another case of extra-genital syphilis, which could be traced to her, he informed the postmaster-general, without being asked by anybody to do so. The patient having consequently lost her appointment and suffered some other inconveniences, claimed damages from the medical man who had, without her consent, disclosed the nature of her disease to a third party. The judge decided that the medical man "had been acting in the public interest, and therefore in defence of the public, conduct which could not be considered a breach of professional secrecy." The defendant was acquitted by the jury. Now there are under consideration certain new medical regulations which stipulate that a medical practitioner must disclose the nature of a patient's illness to a legal authority *if he is asked.* In a similar case a well-known dermatologist recently found that by wilful neglec[illegible] infected his two children, [illegible] tively, and allowed them [illegible] school where they might be a source of infection to others. [illegible] made them wear large patches [illegible] when the school board asked [illegible] answered that the children were suffering from an infectious disease. The consequence was that they were excluded from school until he had given them a certificate of freedom from infection. Of course, there is often a conflict between the duty of the medical man towards the patient and his duties as a citizen. Hitherto it has been an invariable rule with the profession here to consider only the duty of the medical man towards the patient and the law itself was very strict on this point. The development of social life tends, however, to lessen the sense of personal attachment of the physician to his patients in preference to his public duty, though the majority of the profession here show on this point a decidedly conservative tendency.

The Scandal at a Lunatic Asylum.

In a previous letter I mentioned the sad occurrence in one of our lunatic asylums where a patient who had become unmanageable was actually killed by an attendant in the course of "quieting" him. The jury returned a verdict of manslaughter and the attendant, by a series of fortunate circumstances, was sent to prison for only six months. But in the course of the action it became manifest that the real culprit was to be sought for elsewhere. The system was responsible, and public indignation has been only partly allayed by the announcement that the old regulations have been replaced by new ones more in accordance with modern ideas. The false economy of placing only 19 medical men in charge of 3000 insane persons being thus exposed, it is only natural that the number of psychiatric experts in the asylums will be amply increased, and sufficient funds must be found to obtain a better class of attendant than the boards of management has hitherto been satisfied with.

June 14th.

THE CONJOINT DIPLOMA IN PUBLIC HEALTH.—We are requested to state that on and after Jan. 1st next a new syllabus will be adopted for Parts I. and II. of the examination for the Diploma in Public Health of the Royal Colleges of Physicians and Surgeons, and that such syllabus can be obtained on application to the Secretary at the Examination Hall, Victoria Embankment.

Obituary.

DR. CARLO LABUS.

BEARING an honoured name in medicine and in law—son of Dr. Pietro Labus, Director-in-chief of Military Hospitals, and brother of Dr. Stefano Labus, distinguished as a jurisconsult at the Bar and in literature—Dr. Carlo Labus succumbed on June 1st, at his native Milan, to an attack of appendicitis of only five days' duration.

He was born in 1844 and pursued his medical studies at Pavia, where he graduated in 1865. In the following year he served in his country's ranks in the campaign against Austria, filling with much ability and courage the post of army surgeon, and during the cholera epidemic which declared itself after the cessation of hostilities he did valuable service at two such distant centres as Catania and Brescia. Abandoning the medico-military career, he devoted himself exclusively to diseases of the throat, and, in prosecution of his studies, he attended many Continental cliniques—particularly in Austria, Germany, and France—in the pharyngo-laryngeal department. In 1876, by which time he had made himself a name as specialist and consultant in that group of diseases, he initiated at the Medical Congress then held at Turin a "pharyngo-laryngeal section"—the first, it is said, not only in Italy but even in other countries to be instituted at such congresses under that name. In that year he also founded in the Ospedale Maggiore of Milan, the well-appointed "Clinica Laringoiatrico." In 1878 he gave at Pavia the first course of clinical lectures ever held in that seat of learning on laryngology—an initiative which found immediate imitation in other Italian schools, and in 1880 he was president at the first International Congress on Pharyngo-laryngeal Maladies. His distinction in this field brought him many honours in Italy and abroad in the form of "associate" or "corresponding member" of numerous medico-chirurgical societies. Indefatigable in the clinique and in the consulting-room, he found time to contribute a vast number of papers to medical journals on his special subject, papers much esteemed for their independent thinking and expository power. He also invented not a few instruments for surgical intervention in special cases of laryngeal trouble, and some of these are in daily use, particularly in Italy, where also the "Fantoccio Labus," which gained the prize at the Medical Exhibition of Pisa in 1878, still holds the field. Death overtook him while engaged on the concluding chapter of what he meant to be his *magnum opus*, a treatise on "Vocal Hygiene," the publication of which is awaited with much interest by the profession in the ensuing autumn. This, and a selection from his contributions on laryngology to the "Rivista di Medicina," the "Giornale Internazionale delle Scienze Mediche," the "Archives of Laryngology," the "Annales des Maladies de l'Oreille et du Larynx," the "Revue de Laryngologie," the "Archivii Italiani di Laringologia," and the "Gazzetta degli Ospedali," of which last he was one of the founders, will testify to the professional world how much it has lost by the untimely death of the Milanese specialist and consultant, Carlo Labus.

THEOBALD M. BRYSON, L.F.P.S. GLASG., L.R.C.P. EDIN.

AFTER a prolonged illness, Mr. T. M. Bryson died on May 25th at his residence in Limavady, at the age of 65 years. Educated in Glasgow at the University and at Anderson's College, Mr. Bryson became a Licentiate of the Faculty of Physicians and Surgeons of Glasgow in 1868, and of the Royal College of Physicians of Edinburgh in 1874. He began practice in Limavady, county Derry, in 1870. A man of fine physique, genial and social in his habits, and with a sound knowledge of his profession, Mr. Bryson built up a lucrative and extensive practice in Limavady and the surrounding district. He was a justice of the peace for county Derry, and he was also coroner for the district in which he practised. Mr. Bryson was a great favourite with all classes and creeds. He leaves a widow and a daughter who is the wife of Mr. M. Higgins, L.R.C.P. & S. Edin., of Dungiven.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Pribuitkoff, *privat-docent* of neurology in the University of Moscow.—Dr. J. R. Costa, professor of physiology and of medical physics in the University of Buenos Ayres.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Final Examination for the Fellowship held on May 14th, 17th, 18th, 19th, 20th, and 21st 73 candidates presented themselves, of whom 37 were approved and 36 were rejected. Among the successful candidates were three gentlemen (Davis Woodcock Daniels, M.B. Lond., L.R.C.P., M.R.C.S., of St. Mary's Hospital; Charles Henry Shorney Webb, M.B. Lond., L.R.C.P., M.R.C.S., of Middlesex Hospital; and Albert Edward Mortimer Woolf, L.R.C.P., M.R.C.S., Cambridge University and London Hospital) who have not yet attained the requisite age of 25 years. The Council accordingly conferred Diplomas of Fellow upon the 34 gentlemen mentioned below, who have complied with the necessary by-laws:—

Charles Henry James, Major I.M.S., L.R.C.P., M.R.C.S., St. Thomas's Hospital; Carlton Oldfield, M.D., B.S. Lond., L.R.C.P., M.R.C.S., Leeds University; Percy Montague Smith, M.D. Lond., L.R.C.P., M.R.C.S., L.S.A., St. Mary's Hospital; Edmund Arthur Dorrell, L.R.C.P., M.R.C.S., D.P.H. Lond., University College, Bristol, and St. Bartholomew's Hospital; Archibald Hugh Payan Dawnay, L.R.C.P., M.R.C.S., St. Thomas's Hospital; Walter Rothney Battye, Captain I.M.S., M.S., M.B., B.Sc. Lond., L.R.C.P., M.R.C.S., St. Thomas's and St. Bartholomew's Hospitals; Thomas Wi[illegible] Letchworth, M.B., B.C., B.A. Cantab., L.R.C.P., M.R.C.S., [illegible] St. Bartholomew's Hospital; William I[illegible] M.R.C.S., London Hospital; Aaron Levy, B.A., M.D., C.M. McGill, L.R.C.P., M.R.C.S., McGill University, Montreal, and St. Bartholomew's Hospital; John Jekyll Rainforth, M.B. Lond., *L.R.C.P., M.R.C.S., London* Hospital; Herbert Francis Woolfenden, M.D. Liverp., L.R.C.P., M.R.C.S., Liverpool University and London Hospital; Clifford Sidney White, M.D., B.S. Lond., M.R.C.P., M.R.C.S., University College Hospital; Rc[illegible] M.B., B.C. Cantab., L.R.C.P., M.R.C.S., [illegible]d London Hospital; Frank Anderson J[illegible] Cantab., L.R.C.P., M.R.C.S., St. Mary's Hospital; Thomas Charles Clare, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Birmingham University; John Davis Barris, B.A. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; Thomas Bramley Layton, M.B., M.S. Lond., L.R.C.P., M.R.C.S., [illegible] James Eustace Radclyffe McDonagh, L.R.C.P., [illegible]'s Hospital; Sydney Gray Macdonald, [illegible], L.R.C.P., M.R.C.S., St. Thomas Hospital; Hamilton Ernest Quick, M.B., B.S., B.Sc. Lond., L.R.C.P., M.R.C.S., [illegible] St. Bartholomew's Hospital; Rupert Farrant, L.R.C.P., M.[illegible]pital; Alexander Fleming, M.B., B.S. L[illegible] St. Mary's Hospital; James Leonard Joyce, L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's *Hospital*; Christian Frederic Louis Leipoldt, L.R.C.P., M.R.C.S., Guy's Hospital; William Fulton Neil, M.B., Ch.B. New Zealand, L.R.C.P., M.R.C.S., New Zealand University and London *Hospital*; Cecil Frederic[illegible] M.B., B.S. London, L.R.C.P., M.R.C.S., Middlesex [illegible]neth Martin, M.B., B.S. Lond., L.R.C.P., [illegible] College Hospital, Robert Ollerenshaw, [illegible] L.R.C.P., M.R.C.S., Manchester University and London Hospital; Hugh Raymond Guy Poate, M.B., Ch.M. Syd., L.R.C.P., M.R.C.S., Sydney University and London Hospital; Frederick Charles Pybus, M.B., B.S. Durh., L.R.C.P., M.R.C.S., Durham University and St. Bartholomew's Hospital; Vincent Zachary Cope, M.D., B.S. Lond., St. Mary's Hospital; Arthur Cecil Devereux, M.B., B.C. Edin., Edinburgh University and Middlesex Hospital; William Maxwell Munby, M.B., Ch.B. Edin., Edinburgh University and London Hospital, and Laurence Christopher Panting, M.A., M.D., B.Ch. Oxon., Oxford University and Guy's Hospital.

The Diploma of Member was also conferred by the Council upon the following gentleman, who has now complied with the by-laws:—

William John Smith, M.B. Toronto, Toronto University and London Hospital.

Licences in Dental Surgery were conferred upon the following gentlemen who have complied with the necessary by-laws:—

Victor Charles Burt, Charing Cross and Royal Dental Hospitals; Abraham Cohen, Guy's Hospital; Richard Highton, *Liverpool* University; and George Garfield Packe, M.B. Cantab., L.R.C.P., M.R.C.S., St. George's and Royal Dental Hospitals.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Hermann Steudel, who has charge of the Chemical Department of the Physiological Institute, has been appointed Extraordinary Professor of Physiology and Chemistry. Dr. Köllner and Dr. Leber, assistants in the First Ophthalmological Clinic, have been recognised as *privat-docenten* of Ophthalmology. Dr. Doenitz, Assistant in the Surgical Clinic in the Ziegelstrasse, has been recognised as *privat-docent* of Surgery. Dr. Richard Freund, of

Halle, has been recog[illegible] and Dr. Tomasczew[illegible] *Greifswald:* Dr. Lochlein, Assistant in the University Clinic, has been recognised as *privat-docent* of Ophthalmology.—*Vienna:* Dr. Robert BáránBárányi has been recognised as *privat-docent* of Otology.

A CONFERENCE on the Medical Inspection and Treatment of School Children will be held at the Institute of Hygiene on June 21st, when Sir William H. Bennett will preside over a gathering of medical men who have arranged to discuss this important subject.

RESEARCH DEFENCE SOCIETY.—The annual general meeting of this society will be held at the house of the Royal Society of Medicine, 20, Hanover-square, W., on Friday, June 25th, at 5 o'clock. The Earl of Cromer, President of the society, will take the chair. Other speakers will be Sir James Dewar, Sir Arthur Conan Doyle, the Hon. Walter Guinness, and Professor E. H. Starling.

PRESENTATION TO A MEDICAL PRACTITIONER.—After the distribution of medals and certificates to the Helston (Cornwall) branch of the St. John Ambulance Association, which took place recently, the mayor, on behalf of the class, presented Mr. Mark Ronald Taylor, L.R.C.P. Lond., M.R.C.S. Eng., with a silver-mounted ebony walking-stick, which was suitably engraved, in appreciation of his services as honorary lecturer.

THE LONDON COUNTY COUNCIL AND THE MEDICAL TREATMENT OF LONDON [illegible] Committee reported at [illegible] Council on June 15th the [illegible] Sick Children, Great Orr[illegible] treatment for 25 school children per week for a period not exceeding six months, provided that the cases attending on any one day shall be selected so as to avoid placing undue pressure on any one department of the hospital. It is suggested that the cases should be divided between the ophthalmic and aural departments. The Education Committee proposed that children from eight neighbouring schools should be selected to take advantage of the offer, as they thought that an experiment on this limited scale should prove valuable as a guide when the Council deals with the general question of medical treatment. The offer was accepted by the Council.

ROYAL DENTAL HOSPITAL AND LONDON SCHOOL OF DENTAL SURGERY.—A series of post-graduate lectures (as follows) will be given during the months of October and November, 1909, on Tuesdays, at 6 P.M.:—Oct. 12th, "Some Pathogenic Organisms found in the Mouth and their Channels of Infection," Mr. Howard Mummery; 19th and 26th, "Periodontal Disease," Mr. J. F. Colyer; Nov. 2nd, "Stagnation and Drainage," Mr J. G. Turner; 9th, "The Vaccine Treatment in Dental Surgery," Dr. F. A. Bainbridge; 16th, "Dental Radiographs," Mr. Charles A. Clark; 23rd, "Complications arising from Pathological Conditions of the Third Molar," Mr. Warwick James. The fee for the course is £2 2*s*., but past and present students of the hospital and internal students of the University of London will be admitted free.

GUY'S HOSPITAL MEDICAL SCHOOL.—As will be seen by an advertisement in another column applications are invited for a Douglas Research Studentship in Actino-therapeutics. The honorarium of the studentship is £300 per annum, paid quarterly in advance. The following are the main conditions under which the studentship is awarded. The student must possess a registrable qualification to practise under the Medical Acts and will be appointed by the treasurer on the nomination of a special board of electors. The appointment is held during the pleasure of the treasurer for one year. The student must not hold any office or [illegible] or profession [illegible] vent him from [illegible] research. If [illegible] not fulfilling the purposes of the studentship the treasurer will have power to determine that the tenure of the emoluments of the studentship by the student shall cease. The student will [illegible] account [illegible] the [illegible] ater [illegible] three recent testimonials. The successful applicant will commence his work on July 15th, 1909. Further information may be obtained by application to the Dean, Medical School Office, Guy's Hospital, S.E.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The Fishmongers' Company have awarded a University Exhibition of £60 per annum for three years to Miss Naomi Tribe, a student of the school. The council have appointed Miss Kate Brown, M.B., B.S., to be demonstrator in anatomy and Curator of the Museum.

SMOKE ABATEMENT.—The London County Council on June 15th decided, by 98 votes to 2, to promote legislation next year to deal more effectively with the smoke nuisance. The report of the Public Control Committee giving the reasons for this step was dealt with in THE LANCET of May 15th. It is desired to delete from the Public Health (London) Act, 1891, the qualifying word "black" as applied to smoke which may be regarded as causing a nuisance, and to extend the operations of the measure to infringements arising from premises of Government departments, local authorities, and companies having statutory powers. Authority will also be sought to spend not more than £500 per annum in the advancement of measures for the abatement of smoke nuisance, more especially that caused by the domestic open fire.

AMBULANCE COMPETITION.—The competition for the Hamilton Challenge Bowl took place on June 14th at the headquarters of the 5th London Rifles, Bunhill-row, City, and was won by a squad of six men under Lance-Corporal A. Gray, drawn from the 1st City of London Field Ambulance, R.A.M.C.T.F. The subjects included first-aid and stretcher drill, and the competition was open to all the medical units of the 1st and 2nd London Divisions Territorial Force and to all regimental [illegible] were Surge[illegible] Company, [illegible] The challenge bowl was presented by the late Surgeon General J. B. Hamilton, A.M.S., and has been keenly competed for by non-commissioned officers and men of the Volunteer Force for many years. Colonel P. B. Giles, A.M.O., 1st London Division, in announcing the result, stated that the challenge bowl would be held for 12 months by the officer commanding the 1st City of London Field Ambulance and that the conditions of the competition would be changed from time to time.

KING'S COLLEGE HOSPITAL CARNIVAL.—One of the chief features of the carnival which is to be held at the Crystal Palace on July 1st in aid of the King's College Hospital Removal Fund will be the Gipsy Encampment, which is being organised by Mrs. W. S. Playfair. Among those who have promised to lend their aid to this presentation of Romany life are Mr. Jacomb Hood (the artist), Mr. Pett Ridge (the novelist), Lady Florence Pery, Mr. and Mrs. George Alexander and the students of *Old Heidelberg*, Miss Lilian Braithwaite, the Misses Dickens (grand-daughters of the novelist), and Mr. Nigel Playfair. A free flower show is also being organised by Miss Stacey, and two artists and the King's gardener will be the judges. Prizes of silver medals and a silver cup will be awarded in the table decorations competition. Signor Luigi Benedetto and his Italian troop, M. Belenski's Viennese Band, and the Ladies' Forget-me-not Band will also take part in the carnival. We understand that the Gipsy Encampment will be made as realistic as possible and that the artists taking part in it will be specially instructed by gipsies.

THE BOWMAN LECTURE OF THE OPHTHALMOLOGICAL SOCIETY.—[illegible] the Bowman lecture [illegible] Heredity. The sub[illegible] the theories involved and the number of diseases considered, [illegible] ance of hereditary tendencies in successive generations, in first matings, cousin marriages, and the several forms of sex-limited disease, the speaker showed the tendency to anticipate as regards age of incidence in successive generations, both in such general disorders as pulmonary tuberculosis, diabetes, hereditary ataxy, and jaundice with enlarged spleen, and the many diseases of the eye with which he was more directly concerned. These included such widely different conditions as Leber's disease (hereditary optic atrophy), cataract (senile, juvenile, lamellar, and coraliform), glaucoma, retinitis pigmentosa, reticular keratitis, albinism, night blindness, day blindness (total colour blindness), partial colour blindness, and nystagmus. These were considered from the point of view of prognosis as to probable appearance and possibility of recovery, the occurrence of associated disease and early death, and the influence of consanguinity. A notable feature in the general purview was a striking correspondence between the actual figures worked out from collected cases of these several diseases and the theoretical numbers resulting from the application of Mendel's views. The material dealt with was much too extensive for the usual limits of a lecture, even the portions selected occupying an hour and a quarter in delivery. The subject, however, is alive with interest, and the full account of this valuable contribution will appear in the Transactions of the Ophthalmological Society.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Superannuation of Asylum Officers.

THE Select Committee of the House of Commons which has been taking evidence on the superannuation of asylum officers in connexion with Sir WILLIAM COLLINS's Bill on the subject is now in a position to consider the terms of its report. The inquiry has extended over two months and witnesses have been heard from England, Scotland, and Ireland.

The Housing and Town Planning Bill.

The Housing and Town Planning Bill is to be passed through the House of Commons under a closure resolution. The Government has carried a motion allocating three days to the subsequent stages of the Bill. It has already received a second reading. It will be remembered that the Bill was considered at length by a Standing Committee of the House of Commons last year, but it was not further proceeded with then.

The Spirit Duties.

Mr. LLOYD GEORGE has been receiving a series of deputations with regard to the increase of 3s. 9d. per gallon in the spirit duties. The Chancellor of the Exchequer has not committed himself to any modification of this impost, but he has thrown out a suggestion to the Scotch whisky distillers, which if it is ultimately adopted will give an impetus to the maturing of the spirit in bond. Mr. LLOYD GEORGE has asked the distillers to submit to him a plan for levying a graduated scale of duty, which would fall heavily on raw spirits passing into consumption soon after manufacture, but more lightly on those which had been matured for some years. This plan does not meet with the approval of some distillers, but others are favourable to it. They are considering the question and will probably have another meeting with the Chancellor of the Exchequer when they have formed more detailed views on the subject.

HOUSE OF COMMONS.

THURSDAY, JUNE 10TH.

Enteric Germ-carriers Amongst Soldiers.

Captain CLIVE asked the Secretary of State for War whether with reference to the seven non-commissioned officers and men detained at Millbank Hospital as enteric germ-carriers he would state under what section of the Army Act these men were indefinitely deprived of their liberty.—Mr. HALDANE wrote in reply: I have fully explained to the honourable and gallant Member the circumstances under which these men are undergoing special treatment at Millbank Hospital. Papers on the subject will shortly be in the hands of honourable Members. A sick soldier can be ordered to be confined in hospital, and disobedience to such lawful command would be punishable under the Army Act on conviction by court-martial.

C[illegible] BARING also asked the [illegible] gentleman [illegible] officers [illegible] as germ- [illegible] for [illegible] and not [illegible] ary duty or for employ[illegible] t in civil life; and wh[illegible], [illegible] mstances, he would remit the hospital stoppages to which these men were subject.—Mr. HALDANE furnished the following reply: As I have already informed the House, these cases were considered dangerous to their comrades in the barracks and they are, therefore, detained in the interests of all with whom they might otherwise come in contact in civil or military life. In accordance with the regulations in cases of sickness these men have had half their hospital stoppages remitted.

Bulford Camp Hospital.

Mr. JOYNSON-HICKS asked the Secretary of State for War how many men had been sent to Bulford Camp Hospital during the present period of training, how many had been dealt with in brigade and regimental hospital tents, and what proportion of such cases were traceable to preventable causes, such as inadequate supply of tent boards and clothing.—Mr. HALDANE answered: A report has been called for, but the information has not yet reached the War Office.

The Pharmacy Act, 1908.

Mr. SNOWDEN asked the Secretary of State for the Home Department whether he was aware that many licences were being granted under the Pharmacy Act, 1908, to persons other than qualified chemists to sell poisonous substances for agricultural purposes, and that these licences were being granted in large industrial towns where existing facilities were ample; and whether, in view of the definite statement made by the Under Secretary of State on the second reading of the Pharmacy Bill that it was not intended to license traders where the facilities of supply by chemists were ample, he would take steps to prevent the wide and indiscriminate granting of licences to non qualified traders.—Mr. GLADSTONE replied: The Privy Council Office, which is the department [illegible] administering the Act, informs me that there is no [illegible] have disregarded its provisions and [illegible] it is possible that instances of such disregard may [illegible] some localities. The Act charges the local authority with the duty of considering whether the reasonable requirements of the public are satisfied, and these requirements may not in some cases be met by the facilities given by chemists. If the honourable Member knows any cases in which a grievance exists I will be glad if he will bring them to my notice.

Mr. HAYDEN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that in considering applications for licences under the Poisons and Pharmacy Act, 1903, and to assist them in their decisions the county councils of Ireland found it necessary to make inquiries as to whether the applicants fulfilled the conditions laid down in the regulations promulgated by the Lord Lieutenant under the Act and as to the circumstances and needs of the locality; whether they can rely upon the assistance and coöperation of the Royal Irish Constabulary in acquiring this necessary information; and, if not, whether he would state what other machinery was at the disposal of the county councils for securing such information.—Mr. BIRRELL replied: The duty of granting licences is by the Act thrown on the local authorities and any inquiries necessary to enable them to deal with applications should be made by their own officers. The police cannot be asked to undertake the duties of the local authorities in the matter, but no doubt, if asked, they will furnish any information within their knowledge as to any particular applicant which the local authorities cannot otherwise obtain.

Death Certification.

Sir WALTER FOSTER asked the President of the Local Government Board whether his attention had been called to the case of Mary Jane Walker at Wolverhampton, who narrowly escaped premature burial owing to a medical man having given a certificate of her death without having viewed the body; and whether he would take steps so to amend the law with regard to the certification of death as to render such dangers impossible in the future.—Mr. BURNS wrote in reply: I have seen a newspaper report of the proceedings at the inquest in this case. I am afraid I could not undertake to propose legislation on the subject of death certification during the present session.

New-born Calves as Food.

Mr. CATHCART WASON asked the President of the Local Government Board whether he could state the number of newly born male calves that were butchered annually in the United Kingdom and Ireland; whether he had any information showing that these new-born calves were suitable as wholesome food; and if not, whether he had any power to prevent such so-called meat being sold or offered for sale.—Mr. BURNS (by written answer) replied: I am not able to give the figures asked for in the first part of the question, and I am not aware that the information exists. The carcass of a newly-born calf would usually be regarded as unfit for food and would be liable to be dealt with by meat inspectors accordingly. If it was necessary to prevent danger arising to public health from the importation or preparation of these calves when intended for sale for human consumption regulations could be made on the subject under the Public Health (Regulations as to Food) Act, 1907; but I have no evidence at present to show that this is the case.

[illegible]

Mr. COOPER asked the [illegible] ocal Government Board whether he could now state the result of [illegible] inquiry into the action of the officials of the Reading workhouse in the case of Mrs. Emily Chapman, and what he intended to do in the matter.—Mr. BURNS furnished the following written reply: I have obtained a copy of the depositions taken at the inquest in this case and have made inquiry into the matter. It is the fact that Mrs. Chapman was admitted into the workhouse in the evening of May 20th, and was not seen by the medical officer until nine o'clock the next morning. Mrs. Chapman appears to have been seen by the police surgeon before her removal to the workhouse, and the workhouse officers did not think it necessary on her admission to send for the medical officer. She seems to have received care and attention from them, and the medical officer stated at the inquest that he could have done no good had he been sent for on the evening of the 20th. I consider, however, that whenever a case of serious illness is admitted to the workhouse the medical officer should at once be informed by the master. I have communicated this opinion to the guardians and the master has promised to act accordingly in future.

MONDAY, JUNE 14TH.

The Bulford Camp Hospital.

Mr. JOYNSON-HICKS asked the Secretary of State for War how many men had been sent to Bulford Camp hospital during the present period of training, how many had been dealt with in brigade and regimental hospital tents, and what proportion of such cases were traceable to preventable causes such as inadequate supply of tent boards and clothing.—Mr. HALDANE replied: The general officer commanding-in-chief reports that 131 cases have been admitted during the present training period to Bulford military hospital, 261 to brigade and regimental hospital tents, and 39 to the military hospital at Tidworth. As regards the cases in the East Lancashire division 40 have been dealt with in hospital tents. None of these cases are reported to be traceable to preventable causes such as inadequate supply of tent boards and clothing.

The Housing of Miners in Scotland.

Mr. BEALE asked the Lord Advocate whether the Secretary for

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BELL, J., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Lond., has been appointed Principal Civil Medical Officer, Hong Kong, during absence on leave of Dr. J. M. Atkinson.

BREMRIDGE, RICHARD H., B.Sc., M.B., B.Ch. Oxon., L.R.C.P. Lond., M.R.C.S., has been appointed Chief Medical Inspector of Schools for the County of Wilts.

EVANS, DAVID ROBERT POWELL, M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Medical Officer to the North Wimbledon Cottage Hospital.

HEPBURN, MALCOLM L., M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Central London Ophthalmic Hospital.

ISAAC, CHARLES LEONARD, M.B., M.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 30.

JEFFREYS, W. M., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at University College Hospital.

MARTIN, BASIL W., M.B., B.Ch. Aberd., has been appointed Medical Officer to the Reading Dispensary.

PEARSON, J. SIDNEY, M.D. Cantab., has been appointed Pathologist and Registrar to the East London Hospital for Children, Shadwell.

SHERREN, JAMES, F.R.C.S. Eng., has been appointed an Examiner in Anatomy for the Primary Fellowship.

SWEETING, R. DEANE, M.D. Dub., D.P.H. Dub., has been appointed Examiner for the Conjoint Diploma in Public Health of the Royal [illegible] of England.

THO[illegible] .P. Lond., M.R.C.S., has been [illegible] No. 6 District of the Bodmin [illegible]

VOSPER, S., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the British Lying-in Hospital.

WILLIAMS, RICHARD THOMAS, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 30.

WOODWARK, A. STANLEY, M.B., B.S. Lond., M.R.C.P., has been appointed Physician to the Casualty Department of St. Bartholomew's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHLEM HOSPITAL.—Resident House Physician, unmarried, for six months. Salary £25 per quarter, with apartments, board, and washing.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £170 per annum and rooms, fire, lights, and attendance.

BRECON AND RADNOR ASYLUM, Talgarth, Breconshire.—Assistant Medical Officer. Salary £170 per annum, with board, apartments, attendance, and laundry.

BRIGHTON AND HOVE HOSPITAL FOR WOMEN AND LYING-IN INSTITUTION.—Honorary Surgeon-in-Ordinary.

CAIRO, EGYPT, SCHOOL OF MEDICINE.—Professor of Anatomy. Salary £800 per annum, with pension rights.

CANTERBURY BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £140 per annum, with board, lodging, washing, and attendance.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board and lodging.

CHELTENHAM GENERAL HOSPITAL.—Surgeon-in-Charge of the Branch Dispensary. Salary £80 per annum, with board and lodging.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with board, apartments, and laundry.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, washing, and residence.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Also Medical Officer and Second Medical Officer to the Casualty Department, both for six months. Salaries at rate of £100 and £40 per annum respectively with luncheon and tea.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—House Physician for seven months. Salary at rate of £60 per annum, with board, residence, and washing. Also Clinical Assistants in the Out-patient Departments.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

GLOUCESTERSHIRE EDUCATION COMMITTEE.—School Medical Inspector. Salary £250 per annum, with travelling expenses.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Also Assistant House Surgeon. Salaries £100 and £50 per annum respectively, with board, residence, and laundry.

GUY'S HOSPITAL MEDICAL SCHOOL.—Douglas Research Studentship. Value £300.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £30, with board and residence. Also Locum Tenens Bacteriologist and Pathologist. Salary £3 3s. per week.

HULL, ROYAL INFIRMARY.—Honorary Ophthalmic Surgeon.

INDIAN MEDICAL SERVICE, India Office, London.—Twenty-one Commissions.

LEEDS GENERAL INFIRMARY.—Honorary Assistant Surgeon.

[illegible] CHILDREN.—Two Resident Medical Officers [illegible] in each case £30, with board and residence.

[illegible] Brownlow Hill.—Assistant Medical Officer. Salary £120 per annum, with apartments, rations, &c.

LONDON COUNTY COUNCIL.—Twenty-six Assistant School Doctors Salary £120 per annum.

MANCHESTER, UNIVERSITY OF.—Junior Demonstrator in Physiology. Salary £100 per annum.

MOUNT VERNON HOSPITAL FOR [illegible] CHEST, Hampstead and [illegible] Medical Officer at Hamp[illegible] and residence. Also Assi[illegible] wood. Salary £50 per an[illegible]

NEWPORT AND MONMOUTHSH[illegible] Officer. Salary £60 per a[illegible]

OLDHAM INFIRMARY.—Senior [illegible] with residence, bo[illegible]

QUEEN CHARLOTTE'S [illegible] Resident Medical [illegible] annum, with board, residence, and washing.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Junior Obstetr Assistant (female) for six months.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-stree West Strand, W.C.—Assistant Surgeon.

ST. GEORGE'S HOSPITAL, S.W.—Assistant Ophthalmic Surgeon.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—Honorary Assistan [illegible]

ST. [illegible] Welbeck-street, Cavendis [illegible]

SEA[illegible] Salary £100 per annum with board.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medica Officer, unmarried. Salary £100 per annum, with apartment rations, &c.

[illegible] SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—[illegible] six months. Salary at rate of £100 per annum [illegible]

SWITZERLAND, QUEEN [illegible] iden Medical Superinte[illegible] wit board and residence.

UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Assistan Surgeon.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Hous Physician for six months. Salary £30, with board, lodging, an laundry.

Births, Marriages, and Deaths.

BIRTHS.

BARWELL.—On June 14th, at Mildenhall, Suffolk, the wife of Francis R. Barwell, M.R.C.S., L.R.C.P., of a son.

GORDON-GREEN.—On June 13th, at St. David's, 52, Whitwell-road, Southsea, Hants, the wife of Fleet-Surgeon H. W. Gordon-Green, R.N., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

JEWESBURY.—On June 10th, at Stoughton, Guildford, the wife of R. C Jewesbury, M.B. Oxon., M.R.C.P. Lond., of a son.

MARRIAGES.

ADDISON—BROWN.—On June 18th, a[illegible] Church, York Gate, Regent's Park, by th[illegible] Oswal [illegible] Lacy Addison, F.R.C.S., of 55A, [illegible] of Joseph Addison, of 20, Harley House, Regent's Park, and Bond Court, Walbrook, E.C., and Kate (Cissie) Brown, M.B., B.S. Lond., daughter of Harold Brown, of 9, Chester-terrace, Regent's Park, and Bond Court, Walbrook, E.C.

MACNAB—HEWLETT.—On June 12th, at St. Paul's Church, Beckenham, by the Rev. Canon Hammond, John Theodore Macnab, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., of Cambridge House, Balham son of the late Robert W. Macnab, Esq., of [illegible] Violet, fourth daughter of John C. Hewlett, [illegible] House, Beckenham, Kent, and Charlotte [illegible]

[illegible] June 15th, at St. Peter's, Cranley-gardens, South Kensington, Cyril Clarke Boville Morris, A.M.I.Mech.E., Assistant Divisional Officer of the London Fire Brigade, eldest son of Clarke Morris, M.R.C.S., J.P., Blackheath, to Anita, only daughter of Mrs. O'Flanagan, 39, Drayton-gardens, W.

DEATHS.

METCALFE.—On June 11th, at Beccles, Suffolk, Robert Ives Metcalfe, M.D., in his 75th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DENTAL CARIES AND FLOUR.

Mr. T. G. Read, D.M.D. Harvard, has been writing to us and to the press generally, we believe, on the relation of bread to the increase of dental caries. Mr. Read's view is that the increase of dental caries is to be attributed to the alteration of the method of preparing flour. The increase of caries is a question of international interest, and one naturally welcomes any facts which have a bearing upon the solution of the problem. The idea put forward by Mr. Read about roller-milled flour is not altogether new, and it is quite possible that the method of milling of the present day by means of rollers does alter the constitution of bread and make it more rapidly fermentable. Mr. Read's experiments on the amount of acidity produced by bread made with roller-milled and stone-milled flour have a certain interest. They are as follows:—

> He says: "In 1900 I investigated the matter of bread and dental caries, and discovered that there is an increase of about 40 per cent. during mastication in the acidity of bread produced from *roller flour, whereas there is no such increase when the bread is* composed of stone milled flour. These results were confirmed in 1901 by analytical chemists of experience.
>
> Further, I placed in an incubator, at the temperature of the mouth, sound teeth embedded in chewed bread made from roller flour and stone-milled flour. Now, the teeth embedded in the bread made from old-fashioned stone milled flour decayed but
>
> did not eat bread made from roller flour automatically the increase in dental caries would cease."

The experiment recorded by him in his letter is suggestive, and it is to be hoped that he will carry his work forward and try if possible to eliminate all sources of error. If we could feel quite certain that teeth treated in the manner he suggests decay more rapidly with roller-milled than stone-milled flour an advance would certainly have been gained. We are not inclined to think that the increase of dental caries can be put down to this or that special class of foodstuff, and it is much more reasonable to think that the cause really lies in some condition affecting the whole of the carbohydrates that form part of the diet of to-day, and it has been suggested that the trouble in all probability lies in the fact that the carbohydrates of to-day are much more fermentable than they were in days gone by.

THE COURT PHYSICIANS OF EGYPT AND ROME.

The monumental work, the "Histoire des Lagides," by M. Bouché Leclercq, which by utilising the great discoveries of papyrus manuscripts for the first time provides a complete picture of Egyptian times under the Hellenic dominion, gives as a title of one of the *important court functionaries the King's Physician, or βασιλικὸς ἰατρὸς-αρχιατρος.*

This statement carries back the medical Archiatri from the Roman to the Greek epoch, thus reversing the previous pronouncement of classical scholars that the first official known as an "Archiater" was

M. Bouché Leclercq does not note from what document, or record, he has *quoted the title, but there is other evidence proving* the existence of an official royal physician under the successors of Alexander, known as an Archiatrus. The most decisive of these records is an inscription found in the Island of Delos, published by M. Salomon Reinach of Paris. This text refers to a certain Papias of Amisos as Archiatrus to Mithridates. Another record, also upon stone and found at Delos, mentions a medical man who is called Archiatrus of King Antiochus, and so dates from the second century B.C.

The title was first used under the Ptolemies in Egypt and not by the Seleucidæ in Syria because the old Pharaohs from the time of the

who was chief of the physicians of one of the Ptolemies, ἐπὶ τῶν ἰατρῶν, but who fulfilled other functions, one of them being that of the director of the museum. A papyrus at Turin mentions a certain Tatas whom it calls βασιλικὸς ἰατρός, who promul- so that he appears

Aristæus, an

the Hebrew

t), a translation undertaken by desire of Ptolemy Philadelphus in 270 B.C., mentions Ptolemy's Archiatrus, who may well have been connected with the library, because in arranging for the translation of the Hebrew Scriptures he was engaged in a literary congress of Hebrew and Greek scholars. At least one Egyptian papyrus and many newly discovered inscriptions refer to Archiatri of the Roman era.

A FALSE MEDICAL CERTIFICATE IN BERLIN.

A German medical man has been criminally prosecuted for giving a false certificate. *At the urgent request of his patient, a telephone* girl, whom he had attended in her confinement and who declared she would lose her situation if the true cause of her absence from duty were revealed, he at last took pity on her and foolishly consented to certify that she was suffering from influenza and that she would be unable to return to duty for at least eight days. In favour of the accused it was urged that the medical certificate was quite true as to the fact for which it was required—that is, that the girl was too ill to attend to her duty, but the court passed the lowest permissible sentences, viz., one month's imprisonment on the medical man and one day's imprisonment on the girl, but expressed its opinion that circumstances were hard on the practitioner and hinted that perhaps his punishment might be reduced as an act of grace.

A CRUSADE AGAINST FLIES.

To the Editor of The Lancet.

Sir,—Last summer we had quite a swarm of house flies in my house, and they appear to be coming again now. Can you suggest something which will destroy them? If so I should be extremely grateful.

I am, Sir, yours faithfully,
June 14th, 1909. H. K.

*** Our correspondent will find full instructions for using formalin (a solution of formaldehyde) for the destruction of flies in The Lancet of May 22nd, p. 1472, and May 29th, p. 1578, under the heading "A Crusade against Flies."—Ed. L.

OILY INJECTIONS OF BINIODIDE OF MERCURY.

At the present time preparations of biniodide of mercury dissolved in oil are being used widely in the treatment of syphilis. There are some proprietary articles on the market which are claimed to contain 1 per cent. of the mercuric salt, but quite recently it has been shown by Dr. Reid Hunt and Dr. Atherton Seidell in the *Journal of the American Medical Association* that one of these contains less than one part of mercuric iodide in 10,000, and that at ordinary temperatures liquid paraffin holds less than 0·03 per cent. of the salt in solution. In a recent number of the *Répertoire de Pharmacie* Dr. P. Lemaire has given processes for preparing oily solutions of mercuric iodide in various strengths up to 1·5 per cent. He takes advantage of the fact that whereas 100 cubic centimetres of olive oil dissolve and retain in solution only 0·45 gramme of the salt castor oil dissolves

preparing a stable

castor oil, 50 cubic

sufficient to make

erilised and cooled

and care is taken at each stage of the process to avoid contamination. The olive oil is washed with alcohol before sterilisation. The mercuric iodide readily dissolves in the castor oil when heated on a water bath at 70° C. This solution has given very satisfactory results in clinical practice during the past six years. Scarcely any pain is produced by the injections, and they have not been followed by general intolerance, diarrhœa, stomatitis, scars, abscesses, or marked swelling. In some cases nodosities have been produced, but they were of only slight importance. If a stronger preparation is desired it is possible to produce a solution containing 1·5 per cent. of mercuric iodide by using equal parts of

of moisture causes a precipitation of the mercuric iodide, and this rapid dissociation may play an important part when the injection comes in contact with the tissues of the body containing from 74 to 78 per cent. of water. It is quite possible *that the tolerance and* elimination of the injection are prejudicially affected by the addition of potassium iodide.

GIBRALTAR AND ALGECIRAS

Sir F. Evans, Colonial Secretary of Gibraltar, *reporting on the Blue*-book of the colony for 1908, gives the present estimated population (including 5127 military) at 23,443—i.e., 12,949 males and 10,494 females. The death rate for the year was 16·8 per 1000. The number of patients treated in the Colonial Hospital was 531, or 160 less than in 1907. There were only three admissions to the Small-pox Hospital.

there are others who, to escape the rigorous winter in
parts, or recognising Gibraltar and Algeciras as capital centres from which to make tours into Spain and visits to Morocco, remain

temporarily at the hotels. Between Algeciras and Gibraltar there is steam ferry communication at short intervals during each day. This greatly assists communication between the two places. Mr. W James, British Vice Consul at Algeciras, writes to the Foreign Office as follows: "Visitors to this town and to the South of Spain, viâ the Algeciras Railway, are ever on the increase; 58,601 passengers travelled into Spain by train from here during 1908, and the local hotels have been quite full during the season. Undoubtedly Algeciras increases in favour as a health resort year by year, and the general consensus of opinion among visitors is that if only something were done by the Government and local authorities to make the place more attractive the coast of Algeciras Bay would soon become a Spanish Riviera. Algeciras was visited during the year by the King of Spain. It is the first time for over 200 years that the Campo de Gibraltar has been visited by a Spanish monarch. It is rumoured that His Majesty was much struck by the possibilities of Algeciras as a winter resort, and he was graciously pleased to promise a deputation which waited upon him that he would use his influence with the Government to have the condition of the roads improved and their number increased. Up to the present the season has commenced in January and extended to the end of April, but, as a matter of fact, this is the rainy and most unpleasant part of the winter here, and the only cold time in the year is in January and February, when the cold from the surrounding snow-covered hills is very severe. In November and December and the beginning of January the temperature is mild, bright, and dry, and it is a pity visitors do not choose November as the time for coming here. The difference of climate between this place and Gibraltar, across the bay, is quite extraordinary, and even the rainfall differs. In 1908, for instance, it was 30·08 inches in Algeciras and 27·48 inches in Gibraltar. The British residents in Algeciras number about 198."

LYNN THOMAS AND SKYRME FUND.

THE following additional subscription to the fund has been received: D. C. Lloyd-Owen (Birmingham), £1 1s.

◆

A. J. D.—No definite rule can be laid down, and there is no question of correctness It is a matter of courtesy that one medical man should treat another medical man or his family while they are dependent on their father without a fee, but the custom must be regulated by circumstances. For instance, if a medical man is wealthy, or has retired from practice with a sufficiency, there is no reason why he should not pay one of his brethren for medical advice for himself or his family.

Dr. J. Foster Vince.—The name of the medical man about whom our correspondent writes appears in the American Medical Directory for 1906. We have no information other than what we have seen in newspaper cuttings similar to the one enclosed, but we advise our correspondent to urge his patient not to waste her money on a remedy the nature of which is unknown.

R. C.—An analysis of Hollands gin appeared in THE LANCET of July 25th, 1908, p. 243, and attention was directed to its diuretic action.

First Aid.—Permission to give lectures on any subject at a private school rests with the proprietor or proprietors of such school.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		*TO THE COLONIES AND ABROAD.*

THE

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the *ordinary* rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, *Fifth Avenue*, New York, U.S.A.

The Croonian Lectures

ON

RADIO-ACTIVITY AND CARCINOMA: AN EXPERIMENTAL INQUIRY.

Delivered before the Royal College of Physicians of London on June 15th, 17th, 22nd, and 24th, 1909,

By W. S. LAZARUS-BARLOW, M.D. Cantab., F.R.C.P. Lond.,

DIRECTOR OF THE CANCER RESEARCH LABORATORIES, THE MIDDLESEX HOSPITAL, W.

LECTURE I.

[After thanking the College for the honour it had done him in inviting him to deliver the lectures, pointing out that the inquiry was still incomplete and that contributions to the entire research had been made by numerous workers in the Cancer Research Laboratories of the Middlesex Hospital, the lecturer proceeded as follows:—]

The leading idea throughout the whole research has been the undoubted fact that workers with x rays are liable to suffer from carcinoma of the hand. It is unnecessary to labour this point in view of the conclusive evidence furnished by my former assistant, Mr. C. W. Rowntree, in his Hunterian lecture before the Royal College of Surgeons of England on March 17th, 1909. From a careful examination of the microscopical sections shown by Mr. Rowntree I am convinced that he is right in describing the x ray condition which may follow on a somewhat severe and prolonged dermatitis occasioned by exposure to x rays as a squamous cell carcinoma. Into the question of the relationship of the x rays to the carcinoma, whether it is specific and direct or non-specific and, so to speak, accidental, I do not propose to enter here. It will be more convenient to deal with the whole subject at the conclusion of the lectures. For the moment it will suffice to allow that exposure to x rays and carcinoma of the hand are closely related in certain cases.

The next idea of importance in connexion with the research is that for many years certain physical agents have been considered by the profession to be causally related to cancer of special sites. Thus, clay pipes have been associated with cancer of the lip, paraffin and tar with cancer of the hands and arms of workers with these substances, soot with cancer of the scrotum in chimney-sweeps, gall-stones with cancer generally and particularly with cancer of the gall-bladder. In addition, betel-nut chewing[1] has been associated with cancer of the cheek, especially in Ceylon and the East where the habit is common; use of the kangri has been associated with "kangri cancer" in Kashmir; while bilharziosis in Egypt has been held accountable for cancer of the bladder. Similarly it has been noted that cancer occasionally develops on old scars, on the floors of chronic ulcers, and on the sites of lupus.

[illegible] suggested the inquiry [illegible] tar, soot, &c., emit [illegible] active properties. If [illegible] the positive, a single factor would be demonstrated to be present in a group of physical agents differing to the widest degree from one another, and the probability that each particular variety of cancer depended upon the physical agent usually inculpated would be strengthed, while presumption would be raised for the proposition that the common factor in all the physical agents—i.e., their radio-activity—is causally related to the common factor in the pathological conditions to which they all are supposed to give rise—i.e., the cancer.

It is remarkable that the cancer in all the cases that have been mentioned above, with the sole exception of that affecting the gall-bladder, is squamous cell carcinoma. Moreover, the histological diagnosis is almost invariably to be made with great ease, Malpighian cells, prickle cells, and epithelial pearls being conspicuous. For this reason the present research has been confined to the group of carcinomata, meaning thereby squamous cell, columnar cell, and spheroidal cell carcinomata as determined by microscopical examination. The research therefore resolved itself into a determination whether clay pipes, &c., and carcinomatous material give evidence of radio-activity.

The two chief criteria of radio-activity relied on by the physicist are (1) the action of the substance in question upon a charged electroscope; and (2) its action upon a photographic plate in the dark. Of these criteria action upon a photographic plate in the dark is well known to the medical profession in the production of skiagraphs, but it is upon the electrical properties that the physicist places more reliance.

Owing to the fact that the x ray tube only emits γ radiations while such radio-active substances as radium, uranium, and thorium emit α particles, β rays, and γ rays, while they also are far more complex than their chemical names would suggest, it became necessary to consider these substances as well as the x rays. It is clear that a substance may belong to the radio-active group and yet fail to produce γ radiations. Thus "chemically pure" uranium oxide emits α particles and β and γ rays, but the physicist can separate a uranium oxide [illegible] affects a charged electroscope.

In addition to their power of affecting a photographic plate in the dark radio-active substances emitting γ rays with their high velocity and penetrating power or β rays with their somewhat lower but still great velocity and penetrating power, have the property of affecting the photographic plate though separated from the film by such substances as aluminium, mica, &c. This property forms an important means of differentiating the action of a recognised radio-active substance, such as radium or thorium, from other substances which apparently fail to possess the power of acting through a screen. How far this differentiation between radio-active and non-radio-active substances may be carried by this method will be discussed later.

Electrically, the recognised radio-active substances have the property of accelerating the discharge of an electroscope whatever the sign of the electricity with which its leaves are charged. This property depends upon the fact that the radio-active substance by the α particles (helium atoms charged +), β rays (negative electrons), and γ rays which it emits, ionises the air in the electroscope, breaking the molecules up into their constituent atoms, each of which is electrically charged + or −. These charged atoms collide with the charged gold leaves, and such as are of opposite sign to the charge on the leaves neutralise a corresponding amount of electricity on the leaves. The greater the ionisation of the air in a given time the more rapidly the charged leaves fall together and the greater the radio-activity of the substance under investigation is said to be.

From what has been said it follows that the various substances dealt with in the present investigation call for consideration (1) as regards their action when exposed to a photographic plate in the dark, and (2) as regards their influence upon the rate of leak of an electroscope (*a*) charged + and (*b*) charged −. In addition it is necessary to determine the same points in regard to non-carcinomatous substances, and further, to determine the influence of radio-activity upon the division of cells by direct experiment. In the present lecture I propose to show that certain animal tissues and other substances have the power of acting upon a photographic plate in the dark; in the second lecture I shall consider, so far as possible, the properties and nature of the substances in the tissues which possess this power; the third lecture will be devoted to a consideration of the electrical properties of the carcino-[illegible] substances; while the fourth [illegible] fluence of radio-activity upon [illegible] a short general survey of the bearings of the experiments.

The Skotographic Action of Certain Animal Tissues and Other Substances.[2]

If a sample of human liver be minced, dried in the hot air

---

[1] I am informed that the substance used is areca nut powdered and mixed with slaked lime and wrapped in a betel leaf.

[2] I have ventured to extend the use of the word "skotograph" to [illegible]

No. 4478.

oven at 100-110° C., reduced to a powder, and some of this powder be placed on a photographic film in the dark, and the plate and powder be kept in contact in complete darkness for a certain length of time, it will probably be found, on developing the plate, that the former situation of the powder is indicated by a more or less considerable punctate deposition of silver. Prior to development the photographic plate shows no alteration. Similarly if a "pure" cholesterin gall-stone be exposed to a photographic plate in the dark, subsequent development of the plate will probably show an intense deposition of silver which occupies a larger area than corresponds to the area of the calculus in contact with the plate (Figs. 1 and 2). Skotographic action is not manifested by all animal substances; for example, it is rarely produced by spleen or lung dried and powdered as above, while numerous experiments made with uric acid calculi, paraffin wax, and clay pipes have shown that these substances possess no skotographic power. Similarly, certain varieties of micro-organism possess marked skotographic power, while others appear to be totally deficient. It is unnecessary here to enter into the details of the method for obtaining skotographs or the precautions to be taken in order to eliminate the action of light or of any outside influence of a recognised radio-active nature. These are all given elsewhere.[3] It must be stated, however, that the values assigned to the various plates showing skotographic action were determined by comparing them with the effect produced in a photographic plate by allowing x rays to act upon it through a Benoist's gauge. Since the gauge consists of aluminium graduated in thickness from 1 millimetre to 12 millimetres a graduated deposition of silver takes place on the plate. It was possible to graduate the degrees of silver deposition by this means from 0 to 6, and since the same skiagraph was used throughout, the values given for the various substances and tissues are comparable among themselves.

Tissues from non-malignant cases.—In all, tissues from 115 bodies of persons dying from some cause other than malignant disease were examined skotographically. In most instances the examination included samples of liver, kidney, spleen, and lung. The patients were of both sexes and of all ages. They were grouped for purposes of comparison into the following age-periods: "under 2 years" of age, 2–20 years, 21–35 years, 36–45 years, 46–55 years, and "over 55 years" of age. This grouping of age-periods was made in order to institute a comparison with similar tissues derived from cases of carcinoma. In addition to the above, specimens of brain, pancreas, breast, liver of sheep and of ox, tissues of mouse, guinea-pig, and rabbit were examined skotographically, but no reference to the results will be made here.

The results of the investigation are summarised in the following table:—

Table showing Mean Skotographic Values of Liver, Kidney, Spleen, and Lung in 115 Non-malignant Cases.

MALES.				FEMALES.			
Age under 2 years (10 male, 10 female cases).							
Liver.	Kidney.	Spleen.	Lung.	Liver.	Kidney.	Spleen.	Lung.
1·7	2·3	0 8	0 9	3 1	1 6	0 9	1·1
Age 2–20 years (9 male, 6 female cases).							
2·1	2 4	0 6	0 4	3·2	2 8	0 4	0 6
Age 21–35 years (12 male, 10 female cases).							
3 0	2·6	1·1	0·75	3·7	2·3	0 5	0 6
Age 36–45 years (9 male, 10 female cases).							
2·7	1·6	0 3	0 0	3·4	3·9	0 9	0 5
Age 46–55 years (10 male, 10 female cases).							
3·3	1·4	0 5	0 0	4 2	2 7	0 8	0.8
Age over 55 years (11 male, 8 female cases)							
3·9	2·0	0 5	0 9	2·6	2·5	1 1	0 25
Means at all ages (61 male, 54 female cases).							
2·8	2·1	0·6	0·6	3·4	2·8	0 8	0·6

From this table it appears that liver and kidney possess a far higher skotographic power than spleen or lung, and that the female tissue in each case has a greater skotographic power than the corresponding male tissue. Owing to the large size of the liver and to the fact that it exerts the largest amount of skotographic effect, the figures may be examined more closely. It is seen that the skotographic power of the liver in males increases steadily throughout life, with the exception of a fall at the age-period 36–45 years. In females this rise in skotographic power of the liver, including the fall at the age-period 36–45, is also seen. But whereas the values for the male reach their highest in the age-period "over 55 years" this same age-period in females witnesses a remarkable fall in skotographic power of the liver. Further reference to this point will be made in the last lecture. The small mean values obtained for the spleen and lungs are due to the fact that occasionally these organs exert a definite effect. Two-thirds of the total number of spleens examined skotographically, and two-thirds of the total number of lungs, were absolutely without skotographic power. On the other hand, only one-fifth of the total number of livers examined skotographically were without effect.

Carcinomatous material.—The skotographic value of the primary mass has been determined in 17 cases of carcinoma; of secondary growths, 29 specimens from 24 cases have been examined. Eleven of the cases were male, 30 were female. Two primary and four secondary growths were without skotographic effect or the effect was doubtful. The mean skotographic value of the male primary masses was 2·0, male secondary masses, 2·5; that of the female primary masses was 3·6; female secondary masses, 3·2. Hence the superiority of the skotographic value of female tissue over that of male tissue obtains also in the case of carcinoma. (Cf. Figs. 3 and 4.)

Tissues from cases of carcinoma.—The skotographic values of the liver, lung, kidney, and spleen have been determined in 72 cases of carcinoma, 41 of which showed important metastases, and 31 insignificant metastases or none at all. The cardinal facts that liver and kidney exert a greater skotographic power than lung and spleen, and that the skotographic power of a female tissue is greater than that of the corresponding male tissue are shown in this class of case as in that in which there is no malignant disease. But it appears that the carcinomatous condition is not without effect upon the skotographic power of the various tissues. This is best seen by considering the case of the liver.

The effect of carcinoma upon the skotographic power of the liver may be considered in two ways. 1. Livers themselves free from metastasis may be compared skotographically according as they are derived from cases in which the total mass of carcinomatous material in the body is great or is small. 2. A comparison may be made between the hepatic tissue of non-malignant cases and the hepatic tissue of carcinomatous cases in which the liver is the seat of numerous large metastases. These two different methods of approaching the question agree in indicating that carcinoma augments the skotographic power of the liver in males and decreases it in females. In the following table are given the figures upon which this statement is founded:—

Table to show the Influence of Carcinoma on the Skotographic Power of the Liver.

Age.	Males.				Females.			
	Non-malignant cases.	Growth present in liver.	Much growth in body.	Little growth in body.	Non-malignant cases	Growth present in liver.	Much growth in body	Little growth in body.
Under 35	3 0	—	—	—	3·7	2 0	1·7	4 0
36–45	2 7	3 5	2 75	—	3·4	3 5	3·7	4·25
46–55	3·3	3 5	3·5	1·8	4·2	—	3 7	4 0
Over 55	4 0	4 5	4 5	3·8	2 6	2 5	2 5	2 6

But consideration of the above table shows that the matter is not so simple. For although male hepatic substance in the neighbourhood of liver metastases is more skotographic than non-malignant liver, while the converse is true in the case of the female, and although male hepatic substance where there is much growth in the body is more skotographic than when there is little, while the converse is true in the case of the female, a small amount of carcinoma in the body appears to diminish the skotographic power of the male liver, while it augments that of the female liver. I do not attempt an explanation of these points; indeed, they need confirmation on a much larger number of cases. The regularity with which female liver and male liver act in opposite directions in the face of what is apparently a single condition—i.e., carcinoma, is, however, such that it suggests the existence of some sort of interaction between carcinoma and the skotographic property of the liver. On the other hand, we may be quite wrong in considering carcinoma as a single condition relative to the two sexes; it has already been shown that male and female carcinomatous materials differ in skotographic power.

---

[3] Lazarus Barlow: On the Effect Produced by Certain Animal Tissues on [illegible] ark, Archives of the Middlesex [illegible] ancer Report), p. 111. Colwell: Th [illegible] uli upon Photographic Plates in th [illegible] of the Royal Society of Medicine, [illegible] 127.

The only condition in which a thoroughly satisfactory determination can be made of the influence of carcinomatous growth upon the skotographic power of the tissue in which it lies is that in which one of paired organs is the seat of metastasis. This is relatively so uncommon, and when it occurs the chance that the metastasis will be sufficiently large to influence the neighbouring tissue of the organ to any extent is so small, that I have only obtained a single example. The case was one of carcinoma of the cervix, and one kidney was the seat of a fairly large number of metastases while the other was free. The renal substance of the unaffected kidney had a skotographic power of 3, while the renal substance of the affected kidney was absolutely without effect upon the photographic plate. This case therefore conformed to the statement made above for the liver, that in the female carcinoma leads to a diminution of the skotographic power of the tissue in which it lies.

Substances commonly supposed to be causally related to carcinoma.—Numerous samples of clay pipes, soot, pitch, paraffin wax, metallic arsenic, arsenious oxide, areca nut, cholesterin gall-stones, pigment gall-stones, renal and vesical calculi have been examined skotographically, the calculi, renal, biliary, and vesical, being made the subject of an extended research by Dr. Colwell.[4] Skotographic effect was exhibited by one sample of soot out of two examined, by areca nut on all of numerous occasions, by each of 23 specimens of cholesterin gall-stone more or less "pure," in three out of four samples of pigment gall-stones examined, the effect being always very slight as compared with the action of the cholesterin calculi, and by 30 out of 38 vesical calculi. Metallic arsenic and arsenious oxide produced effects upon the photographic plates, but inasmuch as the films showed alteration before development the action cannot be regarded as skotographic. On the other hand, none of nine specimens of clay pipe, of numerous samples of paraffin wax, of four samples of pitch from different localities, of several specimens of coal yielded the slightest trace of skotographic action.

In the case of cholesterin gall-stones the action on the plate extends widely beyond the area of the surface of the calculus in contact with the plate, but in the case of all the other substances the area of silver deposition was co-extensive with the area of contact between substance and film. This is well seen in the skotographs of vesical calculi in which rings of silver deposition alternate with rings of no deposition in such a way that a picture is formed of the surface of the calculus by which the skotograph was produced. (Fig. 5.) When the nucleus of a calculus, or certain laminæ, or the entire calculus consists of "pure uric acid" the corresponding part of the film shows a complete absence of skotographic effect. As a rule, calculi or laminæ in calculi, consisting of urate of ammonium, oxalate of calcium, phosphate of calcium, or ammonio-magnesium phosphate, possessed skotographic power, but since instances to the contrary were found Dr. Colwell concluded that the chemical substances in question, *as such*, were not the effective agent. Similarly, he found that purified cholesterin obtained from a gall-stone which produced a profound effect upon a photographic plate was itself entirely devoid of skotographic power.

Skotographs of areca nut are of especial interest in connexion with the observation made by Dr. Russell, F.R.S.,[5] that almost all varieties of wood affect a photographic plate when placed in contact with it under conditions of total darkness—i.e., possess skotographic powers. This power is possessed by the winter and spring woods in different degrees, so that a skotograph of a piece of wood reproduces a picture of the grain of the wood in the same way as a skotograph of a vesical calculus reproduces the appearance of the cut surface of the calculus. Similarly a skotograph of a bisected areca nut shows the peculiar markings of the nut in all their detail. (Fig. 6.)

LECTURE II.

THE NATURE OF SKOTOGRAPHIC ACTION.

Russell's researches upon the effect of various woods upon a photographic plate in the dark led him to the conclusion that the deposition of silver is occasioned by traces of hydrogen peroxide, formed owing
resinous substances in
This strictly chemical
hydrogen peroxide so minute as to be beyond detection by any other method, is distinguishable from the action brought about by ethereal vibrations, such as those of β or γ rays, by the fact that it is completely inhibited by interposing a thin screen of mica between the wood and the film. Russell showed further that wood which had been exposed to strong sunlight before placing in contact with the photographic film produces a far stronger effect than wood which has been kept in the dark. Under these circumstances it became necessary to determine as far as possible with what constituent or constituents of the animal tissues their skotographic power was bound up, and subsequently whether that power conformed more to the type of a chemical substance, and particularly to hydrogen peroxide, or more to that exerted by ethereal vibrations. It must be stated at the outset that a complete answer cannot be given to the above questions. It can rather be said what the skotographic power is *not* bound up with than what it *is*. Similarly it will be found that it is impossible to include it definitely in the chemical or the physical group of phenomena, since in certain respects it appears to resemble hydrogen peroxide, and in others to resemble an ethereal vibration.

Attempts at isolation of the skotographic substance.—The skotographic substance, or substances, for there is reason to believe that in the liver at least two substances exist which differ from one another in certain reactions, but agree in affecting a photographic plate in the dark, is not protein, or fat, or carbohydrate, or colouring matter, or mineral salts. Each of these constituents of the tissues has been definitely excluded. It is unnecessary to enter into a detailed account of the method in which this has been done, for it has been recorded elsewhere.[6] The following short account will suffice. That it is not *protein* is indicated by the fact that it is yielded by liver, for example, and not by spleen; while the same fact shows that it is not dependent upon the "cellularity" of the tissue as such. But the non-protein character can be shown by obtaining a completely protein-free extract of the tissue and proving that this extract still possesses skotographic power. Fig. 7 shows that this is the case. It was produced in the following way. Liver of sheep was minced and allowed to stand under distilled water for 18 hours. The watery extract was then acidified, boiled, and filtered. To the filtrate three times the volume of basic lead acetate in solution and suspension was added and the resulting precipitate was filtered off. Then sulphuretted hydrogen was passed through the filtrate to precipitate the lead, and after the filtrate from this operation had been concentrated to small bulk upon a water bath it was added to twenty times its volume of absolute alcohol and allowed to stand for three weeks. The merest trace of precipitate was formed and was filtered off and the alcohol was removed by evaporation. The residual fluid was then used to write certain words on a plain glass plate with a camel-hair pencil, and this plate was exposed to the photographic film under skotographic conditions and separated from contact with the film by strands of cotton. It is seen that this watery extract of liver in which none of the laboratory tests for protein shows the slightest trace of the material possesses intense skotographic power. The process for purification from protein has been checked at every stage as well as the reagents used, and it is certain (1) that the skotographic power is not introduced during the process; and (2) that the various precipitates formed are devoid of skotographic power except in so far as they are contaminated with the corresponding filtrate.

That the skotographic substance is not *fat* as such is shown by the fact that a material which has been rigidly extracted with ether still possesses skotographic power. Thus all the powdered tissues that were used to arrive at the conclusions given in the first lecture were extracted with pure ether in a Soxhlet apparatus for a minimum of six hours before being examined skotographically. This method extracts the phosphorised as well as the non-phosphorised fats. Just as the watery extract of a liver, for example, possesses skotographic powers, so it is possessed by an ethereal extract. Into the question of the actual constituent of the ethereal extract which possesses the power it is impossible for me to enter. The chemical analysis I have not attempted owing to its difficulty. That the skotographic substance is not *carbohydrate* as such is proved by the facts that some of the extracts by which it is manifested contain carbohydrate while others are devoid of it, that it is manifested by ethereal extracts, and, as will be shown later, that it survives charring. The fact that the skotographic power is independent of the water-soluble and the ether-soluble *pigments* of the tissue is shown by the persistence of effect if one of these extracts be decolourised by finely divided animal charcoal. And finally, that it is independent of the *mineral constituents* of the tissue, at least those which survive a temperature of 300° C. (see below), is shown by the fact that the ash of a tissue which possesses marked skotographic power is entirely without effect upon a photographic plate in the dark.

The skotographic power of any tissue is completely removed if it be first extracted with water and subsequently with ether. This appears from the accompanying figure in which the upper fourth shows the effect of the original substance; the second fourth shows the effect of a watery extract; the third, that of an ethereal extract made subsequently to the watery; the bottom fourth, over which there is an absence of skotographic action, was exposed to the solid residue after the watery and ethereal extractions (Fig. 8). A similar absence of skotographic power characterises a tissue which has been extracted with acetone as might be expected since it dehydrates and also extracts fat. Just as the skotographic power is contained in the watery and ethereal extracts, so it is contained in one made by acetone, and by evaporating with care the constituents of the original skotographic material which are soluble in water and those which are soluble only in strong acetone may be divided. They are apparently the same as those which are contained in the watery and ethereal extracts when these are made separately.

But though it is clear that the skotographic power is not a property of protein as such, there is no doubt that it is a property of certain organic substances, as distinguished from inorganic, that are probably derived from protein. As will be shown later, the skotographic power is not destroyed, even though the substance manifesting it be heated to a temperature of 300° C. Such a temperature chars the substance and no doubt breaks up much of the protein, but from it a material, often of polymorphic crystalline character but highly deliquescent, can be separated which exerts a skotographic effect and which is still organic in nature, as shown by the fact that it chars on further heating. By repeated solution in water and precipitation with absolute alcohol, this crystalline material can be divided into a honey-like non-crystallisable and a colourless crystallisable portion. The skotographic power resides chiefly, if not entirely, in the honey-like, highly deliquescent material. This material is dialysable with ease and carries with it the actual skotographic substance. Further than this analysis has not gone.

Conditions determining the manifestation of skotographic power by substances possessing it.—It has been shown above that I have not succeeded in isolating the skotographic substance, though it has been stripped of certain materials with which it is usually associated. It has therefore been necessary to investigate the skotographic property upon crude material, and for this purpose the ether-extracted, dried, and powdered original material and watery extracts that have been freed from protein in the way already described have chiefly been used.

Relation of substance to the photographic film; contact; proximity; screens.—All the skotographic effects to which reference was made in the first lecture were obtained by allowing the powdered substances to lie in actual contact with the photographic film, but there is no doubt that they can act at a little distance. This is better seen in considering the watery extracts, for when they were under investigation contact with the film was necessarily excluded. Attempts were made to determine the maximum distance at which recognisable skotographic effect is produced by exposing a glass plate bearing the watery extract to the photographic plate at an angle. In this way, and using photographic plates specially sensitised for x-ray work, it was found that the watery extract used for producing Fig. 7 is still effective when it is separated from the film by a distance of 15 millimetres.

The question of screens between the material and the photographic film is one of fundamental importance in trying to arrive at a conclusion as to the nature of skotographic action, and must therefore be dealt with in some detail. It may be stated at the outset that interposition of a screen of the order of thickness of that used in examining the effects of recognised radio-active materials, such as uranium or thorium, between the animal substance under investigation and the photographic film completely eliminates skotographic action. This is true whether the screen be metallic (e.g., aluminium) or non-metallic (e.g., mica), however intense the skotographic action may be in the absence of a screen, or however long (up to six weeks) the exposure may have been, and even though it have been carried out at 55° C.

On the other hand, the matter is not simple, as the following experiments show. If a flat section of an areca nut or of liver be coated with a thin film of celloidin and the whole be exposed to a photographic plate in the ordinary way it will be found that the greatest deposition of silver occurs on that part of the plate which was separated from the substance by the celloidin. That this effect is not due to the celloidin itself is shown by the fact that an old film of celloidin is entirely without skotographic effect, and in the areca nut experiment the celloidin had been painted on the nut two years before it was exposed to the photographic plate. (Fig. 6). In the second place, if an albuminate of thorium be made by allowing a solution of the nitrate to fall into egg-white the resulting precipitate after drying and powdering fails to affect a photographic plate through a film so thin as that produced by brushing a minute quantity of egg-white over tissue paper, though a fair deposition of silver occurs when the albuminate is separated from the photographic film by tissue paper uncoated with egg-white. Such an albuminate of thorium contains about 10 per cent. of the radio-active element by weight. Even in this case it is possible that such direct skotographic effect as was produced was due to uncombined radio-active salt, since the precipitate was not washed for fear of hydrolysis. In several instances where the precipitate with thorium was washed

thoroughly with hot water before drying it failed to produce an effect upon the photographic plate, even though it were actually in contact with it during exposure; nevertheless, such samples of albuminate showed the presence of considerable amounts of thorium on analysis. Hence under special conditions a vegetable or animal tissue may produce skotographic action through a thin film of celloidin, and a radio-active substance may fail to affect a plate through a film of egg-white of probably even a greater tenuity.

Effect of temperature.—Within the limits of – 3° C. and 100° C. it may be said that the skotographic action of the tissues is independent of the temperature provided that the exposure be longer at the lower temperatures. Thus, a degree of silver deposition which can be attained by exposing a cholesterin gall-stone for 18 hours at 55° C. to the photographic plate can only be attained after an exposure lasting for weeks at the room temperature and probably for several months in the ice-chamber at – 3° C. Exposure of the substance to a plate at a dry heat of 100° C. is an unsatisfactory procedure, but if the exposure be shortened to about half an hour silver deposition is not general but is confined to the part with which the substance under investigation was in contact. The general temperature at which the skotographs in this research were taken was 55° C., and the length of exposure was 18 hours. Except in certain cases imperial special rapid plates were used and development was by 1—20 Rodinal.

Above I have dealt with the temperatures at which the substance has been exposed to the photographic plate, but the substance itself may be exposed to a much higher temperature without undergoing complete loss of skotographic power. I have not been able to determine with exactness the highest temperature to which a skotographic substance may be raised without undergoing complete loss of its power, *but it is certain that a skotographic watery extract painted* in a thin layer upon a No. 1 coverslip and exposed to dry air at about 280° C. for five minutes will probably afford evidence of skotographic power, while a *similar* coverslip exposed to about 300° C. will not. In any case it is certain that the skotographic power is not destroyed by a temperature (about 200° C.) which chars the substance itself and therefore in large measure disintegrates it.

Leaving on one side such points as the fact that the change in the photographic plate is not due to the hygroscopic character of the partially purified photographic substance, the gradual disappearance of the power on continued exposure to air, the curious way in which occasionally there occurs a recrudescence of skotographic power in a watery or acetone extract, the fact that the power is independent *of the acidity, basicity, or neutrality of a* watery extract, points which have been made the subject of many experiments and are of great theoretical interest, I pass to *certain experiments instituted in order to compare* the photographic power of animal tissues with that manifested by woods and held by Russell to depend upon the presence of hydrogen peroxide.

Light and darkness.—Russell found that the skotographic power of a wood is profoundly influenced according as it has been exposed *to light, and especially direct sunlight*, or has been kept in darkness before exposing it to the photographic plate. *If exposed to light the skotographic power is always intensified*; if kept [illegible] In the case of animal t[illegible] this point has been [illegible] Colwell respectively. [illegible] do not show the slightest difference in skotographic [illegible] even though they may be exposed to direct sunlight or be *preserved in total darkness for* a period of six months before placing them in contact with the photographic film.

Volatility.—Inasmuch as the [illegible] power of an animal *substance disappears* after [illegible] exposed freely to air it was though[illegible] due to some volatile product. A[illegible] difficult *to imagine* a volatile subs[illegible] a temperature of 300° C., lower than which the skotographic power is not destroyed the question has been approached direct[illegible] cedar [illegible] to im[illegible] volatility, as such, is not the effective cause [illegible] effect since a skotographic effect was produced in the case of air charged with the volatile products of oil of cedar wood alone. Further, it has never been found possible to carry [illegible] used in [illegible] volatile [illegible] d in the stream of air impinging upon the photographic film by the sense of smell. Fig. 9 shows the skotographic effect of a current of air charged with the volatile products of cedar wood oil.

Experiments bearing on the question whether skotographic action is essentially due to hydrogen peroxide.—These are of two kinds. In one set Colwell took a cholesterin gall-stone which yielded a profound skotographic effect and prepared from it a sample of purified cholesterin. Examined skotographically this purified cholesterin was absolutely without effect. He now exposed a thin film (made by dissolving the cholesterin in chloroform, pouring on a glass plate, and allowing the chloroform to evaporate) to an atmosphere fully charged with hydrogen peroxide vapour for 24 hours at a temperature of 53° C. Similarly he exposed to hydrogen peroxide vapour a vesical calculus normally possessing no skotographic power. He found that now both cholesterin and vesical calculus affected the plate profoundly, but that within 23 hours of their removal from the atmosphere of hydrogen peroxide they had completely regained their original freedom from skotographic power. Probably the last traces of hydrogen peroxide had disappeared long before 23 hours, but of this there is no proof. This experiment bears upon the length of time during which skotographic power is held by a substance, a subject which will claim our attention shortly.

The second set of experiments concerns the so-called peroxydase effect shown by certain tissues. In its best known form the peroxydase reaction is represented by the guaiacum test for blood. It depends upon an oxidation of the traces of guaiaconic acid present in the freshly prepared tincture of guaiacum by oxygen that has been set free from hydrogen peroxide by a substance (peroxydase) present in the substance undergoing the test.

In examining a large number of dried and powdered tissues from this point of view as well as from that of their skotographic power I found, speaking generally, that the degree of peroxydase reaction manifested by them and measured against a standard graduated series of blue solutions varies inversely with the skotographic power. This is seen in the two series of ten consecutive specimens given below.

No.	220	221	222	223	224	225	226	227	228	229
Tissue	K.	Lg.	Lr.	K.	Lg.	S.	Lr.	K.	S.	Lg.

Peroxydase value	2	4	3	5	0	6	1	4	5	6

K. = kidney; Lg. = lung; Lr. = liver; S. = spleen.

This fact would seem to indicate that a tissue possessing a large amount of a substance which splits up hydrogen peroxide has but littl[illegible] power, and conversely that a substance exer[illegible] contains but little of the [illegible] perty. From this it is but a step to the conclusion [illegible] ussell, that the skotographic property is in reality nothing more than a manifestation of the *action of hydrogen* peroxide upon a photographic plate. But that this conclusion is not justified is shown by two sets of observations. Firstly, I have found that *skotographic effect* may be shown by watery [illegible] to end of their exposure to the [illegible] oxydase, and are therefore in a condition to split up [illegible] hydrogen peroxide that may be formed immediately on its production. And secondly, the inverse relations of peroxydase and skotographic power do not obtain *for dried* and powdered carcinomatous material, for such material, whether it produce a great skotographic effect or a slight one or no effect at all, is devoid of peroxydase. Amongst 17 samples of dried and powdered carcinomatous material examined for the purpose only four contradictions were found. One of these is explicable by the fact that the growth was a pulmonary metastasis and probably contained some pulmonary tissue, which has, normally, a high peroxydase co-efficient, and the remaining three, all of which were hepatic metastases, gave the least recognisable amount of peroxydase.

Duration of skotographic power.—Strictly speaking, the length of time during which a substance retains skotographic power can only be determined in the case of such materials as have actually been prepared. Thus, the material used in the production of Fig. 7 was prepared on March 24th, 1908, and inasmuch as a skotograph taken with the same substance a year later (Fig. 10) also shows effect, it is clear that the substance in question retained the power for that length of time. Numerous skotographs taken at intermediate times show that the power has been present throughout. From the time of its preparation the substance was kept in a clear stoppered bottle in the laboratory without any special precautions. This experiment renders it probable that a substance which at any time shows skotographic power also possessed it at the time of its original formation, and this assumption becomes of importance in connexion with the skotographic power of calculi. Colwell has shown that cholesterin calculi will often produce intense skotographic action directly after their removal from the body, but he has also shown that intense skotographic power may be shown by a cholesterin gall-stone that has been preserved in the museum of the hospital for over 25 years. In the case of vesical calculi he goes much further, for a calculus removed by Percival Pott, who died in 1788, shows well-marked skotographic power (Fig. 11), and faint but definite skotographic power is shown by a calculus removed from the body of a predynastic Egyptian mummy and therefore at least 7000 years old.[7]

Use of photographic plates specially sensitised for x ray work.—Recently plates have been placed upon the market which are specially sensitised for x ray work. It was thought that a series of comparative tests of the same substances, when exposed to these and to ordinary plates, might indicate whether the skotographic power of the substance under examination was more akin to light or to x rays. Dried, powdered, and ether-extracted carcinomatous material from a metastasis in the liver and ordinary deal sawdust were examined in this way. It was found that the first appearance of action on the x ray plate occurred at the end of the sixth hour of exposure and on the "Imperial special rapid" plate not till the end of the seventh hour (the powdered growth being separated from the photographic films by thin layers of filter paper), and that the ultimate density of silver deposition was greater also on the x ray plate. When the material was not separated from the photographic film by filter paper the first appearance of action was observable on both plates at the end of the first hour of exposure, but whereas it was quite marked on the x ray plate it was only just distinguishable on the other. In the case of sawdust these differences did not show themselves, the deposition of silver on the ordinary plate being very nearly, though not quite, as intense as that on the x ray plate. (Figs. 12 and 13.)

Skotographic action of bacteria.—MacCormac[8] has published the results of an investigation into the question whether skotographic action is exerted by bacteria. He examined in this respect 27 different varieties of micro-organism, and from his table they may be grouped as below:—

Group I. No skotographic action.—B. Rabinowitch. B. Cohn I. B. Gärtner. B. phosphor. albiensis. B. intestinalis sporog. B. Danysz. B. mycoides. B. coli. V. choleræ.

Group II. Skotographic action fickle.—Sarc. flava. B. Flexner. V. Metchnikovi. B. Hoffmann. B. Megaterium. M. citreus agilis. B. pyocyaneus. B. phlei II. B. prodigiosus. B. typhosus.

Group III. Skotographic action usual and considerable.—Staph. pyog. aureus. Staph. pyog. albus. B. tuberculosis. B. tuberculosis bovinus. B. diphtheriæ. "Pathogenic throat yeast." The importance of these researches will be indicated later.

Summary.—In this and the preceding lecture I have shown that certain of the tissues of the human body show skotographic action (liver, kidney), while certain do not (spleen, lung); that a larger amount of this property resides in female tissues that possess it than in male of the same kind; that the amount present in the liver increases from infancy to the age of 55 years with an unexplained drop in both sexes during the age-period 35-45, and that after 55, while it increases still further in the case of males, in females it undergoes a sharp diminution. I have shown that carcinomatous material possesses skotographic power, whether it be primary or secondary, and that female carcinomatous tissue has a higher skotographic value than male; and that the existence of a mass of carcinoma in a tissue modifies its normal skotographic value. I have found that certain substances commonly supposed to be causally related to carcinoma possess the skotographic power to a high degree (cholesterin gall-stone), while others are devoid of it (clay pipe, paraffin). I have endeavoured to throw some light upon the nature of the skotographic action manifested by animal tissues and certain other substances, comparing their behaviour with that of woods in which the action has been regarded as dependent upon the formation of hydrogen peroxide, and with that of recognised radio-active substance. On this point I have adduced evidence showing that the animal tissues and other substances under examination cannot, as far as their action upon a photographic plate in the dark is concerned, be grouped conclusively with the recognised radio-active substances or segregated into a class, such as that formed by the woods, and believed by Russell to affect a photographic plate in the dark by means of a purely chemical action. They occupy an intermediate position and have affinities with the woods on the one hand, and with the recognised radio-active substance on the other. Lastly, MacCormac, working in my laboratory, has shown that bacteria may be divided into groups according to their skotographic power and that the only group which acts in this way with constancy and to a marked degree is a small one which includes the pyogenetic staphylococci and the bacilli of tuberculosis and diphtheria. The bearing of these observations upon the question of carcinoma must be left for consideration in the last lecture.

LECTURE III.

THE ELECTRICAL PROPERTIES OF RECOGNISED RADIO-ACTIVE SUBSTANCES, OF NON-MALIGNANT TISSUES, OF CARCINOMATOUS MATERIAL, AND OF CERTAIN SUBSTANCES COMMONLY SUPPOSED TO BEAR A CAUSAL RELATION TO CARCINOMA.

THE researches to which I am now about to refer have been in progress for the past three and a half years nearly continuously. This length of time was necessitated partly by the importance of controlling certain of the results, but mainly by the fact that the differences between the control and the experimental conditions are so small that special care was necessary for their determination. The rate at which the electricity on charged gold leaves leaks from them is dependent upon so many factors that unless the extrinsic causes of leak are reduced to the lowest possible point small intrinsic differences are entirely lost sight of. Electroscopes in which the natural leak is greater than about one millimetre per hour are quite useless for the purpose; in the majority of the cases the charged leaves approximated over a fixed distance at a rate of about 0·6 millimetre per hour and in a large number the rate was about 0·2 millimetre per hour. It follows that the length of time necessary to obtain a single observation, whether control or experimental, is considerable; in no instance has it been possible to obtain more than one observation per day and in certain of the experiments it took two days to obtain each observation. This difficulty was obviated to some extent by using several electroscopes. As a rule, two control electroscopes (charged + and − respectively) and eight experimental electroscopes (four charged + and four charged −) were under observation.

It is unnecessary to enter here into a description of the apparatus or of the precautions taken; they are sufficiently

---

[7] This calculus is preserved in the Museum of the Royal College of Surgeons of England and was kindly lent by Mr. Shattock. Owing to its unique character it was impossible to deal with it as with other specimens. Hence a flat surf[illegible] could not be placed in contact with the photographic film. Th[illegible] al skotograph was shown during the lecture, but the ma[illegible] finite, are too faint for reproduction [illegible] without re[illegible] ch is, of course, inadmissible.

[illegible] spital, 1909, vol. xv. (Eighth Cancer described elsewhere.[9] Similarly it is unnecessary, in the majority of cases, to refer to the actual experiments. It will suffice to state that the object of the research was to determine whether the leak of a fully-earthed lead electroscope differed according as it did not contain or contained one of the substances under investigation.

The substances examined were liver, kidney, lung, and spleen (four specimens of each) from non-malignant cases, four specimens of hepatic substance from livers the seat of carcinomatous metastasis, four specimens of the inorganic constituents [illegible] cases, four specimens of [illegible] from cases of carcinoma, [illegible] as the seat of secondary growth, and 12 specimens of carcinoma. Of substances supposed to be causally related to carcinoma the following have been examined electrically: three samples of clay pipe, each sample consisting of portions of three distinct [illegible] of paraffin wax, three samples of areca nut, and one sample each of metallic arsenic, arsenious oxide, and coal. In addition to the above, experiments have been carried out in connexion with the recognised radio-active substances uranium, thorium, and pitchblende, in order to throw light, if possible, upon certain unexpected electrical phenomena.

In the case of the carcinomatous material diagnosis was always made microscopically. Four cases were primary (cervix, cervix, tongue, and breast) and eight metastatic. Of the latter, six came from the liver, the sites of the primary growth being rectum (three cases), breast (two cases), stomach (one case); the remaining two were pulmonary metastases from cases of mammary carcinoma. The substances were introduced into the electroscopes in the dried powdered state to which they had been reduced for skotographic examination.

Results of experiments.—In the case of carcinoma material which has been extracted with water and subsequently with ether, or has been extracted once and for all with acetone, there is strong evidence that the leak of the electroscope is accelerated, and that, whether the charge on the leaves be + or −. Similarly, there is evidence that the inorganic constituents of bone, whether taken from non-malignant or from carcinomatous cases, accelerate electroscopic leak, whether the charge on the leaves be + or −. And thirdly, clay pipe, and possibly one sample of soot, acted in an identical manner.

So far, therefore, there is evidence to satisfy the physicist that the substances mentioned above are "radio-active" in the physico-chemical sense of the term. But already difficulties have arisen, for whereas the carcinomatous material produces skotographic effects when it has been extracted with water alone or with ether alone, it fails to do so when it has been extracted with both, or with acetone, while the inorganic constituents of bone and the clay pipe are equally non-skotographic.

The difficulty becomes much greater, however, when it is f[illegible] accelerating [illegible] *be + or —.* I make this statement with a full sense of the [illegible] physicist [illegible] ctivity," [illegible] eoretical [illegible] d radio- [illegible] smaller [illegible] elements with high atomic weight from elements with lower atomic weight. But I have carried out the experiments with the utmost care of which I am capable and have found evidence of anti-radio-activity a *sufficient* number of times to be convinced of the accuracy of my observations. Moreover, as the following experiments will show, I believe that evidence of anti-radio-activity may be obtained by the use of recognised radio-active substances themselves.

If an aluminium disc be kept in close proximity, but not in contact, with uranium or thorium or pitchblende for 48 hours under fully earthed conditions, and its influence upon electroscopic leak after such exposure be compared with its influence before exposure, it will be found, I believe, that the rate of leak has become retarded. This retardation persists for many days and is independent of the sign of the electricity with which the leaves are charged. Full details of the experiments are given elsewhere;[10] it will suffice to give here a summary of the results obtained in an experiment lasting over four months and carried out in order to re-investigate the question owing to the adverse criticism to which the first set of experiments had been exposed. This second experiment completely confirmed the first.

Experiments showing that an Aluminium Disc which has been kept in proximity to a recognised Radio-active Substance has acquired Retarding or Anti-radio-active Properties on Electroscopic Leak. The Values are the Mean Differences between the Experimental and the Control Electroscopes.[11]

I. Electroscope in which was examined the aluminium disc placed in proximity to uranium nitrate.

Control period.	Blank experiment.	Actual experiment.
− 25 mm.	− 25 mm.	− 27 mm. (29 observations for retardation to 10 for acceleration.)

II. Electroscope in which was examined the aluminium disc placed in proximity to uranium oxide.

Control period.	Blank experiment.	Actual experiment.
+ 86 mm.	+ 85·5 mm.	+ 82 mm. (36 observations for retardation to 9 for acceleration.)

III. Electroscope in which was examined the aluminium disc placed in proximity to pitchblende.

Control period.	Blank experiment.	Actual experiment.
− 18 mm.	− 21·5 mm.	− 26 mm. (44 observations for retardation to 2 for acceleration.)

IV. Electroscope in which was examined the aluminium disc placed in proximity to thoria.

Control period.	Blank experiment.	Actual experiment.
− 31 mm.	− 34 mm.	− 38·5 mm. (37 observations for retardation to 9 for acceleration.)

Note.—In the case of thoria the observed acceleration occurred on the first four days of each of the two parts of which the actual experiment consisted and was evidence of the well known "induced radio activity" due to thorium.

The following experiment shows that a similar retarding property is conferred [illegible] disc that has been placed in proximity [illegible]

V. Electroscope in which was examined the aluminium disc placed in proximity to a cholesterin gall-stone.

Control period.	Blank experiment.	Actual experiment.
− 3 mm.	− 4 mm.	− 8 mm. (41 observations for retardation to 5 for acceleration.)

Returning now to a consideration of carcinomatous material itself, it appears that the electrical properties differ according as the substance has or has not been extracted before its influence upon electroscopic leak is determined. Moreover, the extract exerts a definite influence upon the leak and that influence is in the opposite direction to that exerted by the extracted substance. This is shown by the following table condensed from one given by me elsewhere.[12]

---

[9] [illegible] Cancer Report).

[10] Loc. cit.

[11] Cf. Archives of Middlesex Hospital, vol. xv., 8th Cancer Report, 1909, p. 145.

Table showing the Influence upon Electroscopic Leak of Four Specimens of Carcinomatous Material Before and After Extraction, and of the Extracts Themselves.

—	I.		II.		III.		IV.	
Charge on gold leaves	−	+	−	+	−	+	−	+
Carcinoma, dried and powdered ...	A	A	R?	O	A	O	A	O
Above after extraction with ether...	A	A	R	A	A	A	A	A
Above after extraction with ether and subsequent extraction with water	A	A	A	A	A	A	A	A
Ethereal extract of above	R	R	R	R	R	R	R	R
Watery extract of above after its extraction with ether	R	R	A?	R	A	R	R	R

"A" is used to signify acceleration; "R," retardation; and "O," zero.

The manner in which the uncertain influence upon electroscopic leak exerted by the substance when simply dried and powdered gives place to an increasing evidence for an accelerating power after each extraction, the powerfully retarding character of the first extract and the less powerful but still distinctly retarding character of the second afford a chain of evidence, not only for the existence of "anti-radio-activity" but also for the presence of both forces in carcinoma tissue, that cannot lightly be dismissed. So far as concerns the accelerating influence of carcinoma material after extraction, the conclusion given above is supported by the results of examining electroscopically eight other specimens extracted with acetone.

While carcinoma tissue after extraction accelerates the leak, this is not the case with liver or lung from non-malignant cases. These extracted tissues were found uniformly to retard leak. The acetone extract of non-malignant liver, however, agreed with that from carcinoma tissue in retarding leak, and the unextracted tissue showed a less tendency to induce retardation than the extracted. Below are given the results obtained with four specimens of liver from non-malignant cases.

Table showing the Influence upon Electroscopic Leak of Four Specimens of Liver from Non-malignant Cases Before and After Extraction and of the Extracts Themselves.

—	I.		II.		III.		IV.	
Charge on gold-leaves	−	+	−	+	−	+	−	+
Liver, dried and powdered	A	R	R?	R	R	R	R	R
Above after extraction with acetone	R	R	R	R	R	R	R	R
Acetone extract	R	R	R	R	R	R	A	A?

"A" signifies acceleration, "R," retardation

In the first lecture evidence was given to show that the skotographic action of an organ which is the seat of carcinomatous metastasis differs from normal. Examination of four specimens of hepatic tissue from livers the seat of carcinomatous metastasis shows that the new growth also influences the electrical properties. Thus in the table immediately preceding, the evidence for retardation exerted by the four specimens of acetone-extracted liver (each of which retarded the leak whether the sign on the leaves was − or +) consisted of 76 individual observations of retardation to four of acceleration. In the case of hepatic substance from livers the seat of carcinomatous metastasis, not only did two of the specimens show discordant results affording evidence of acceleration in the electroscope charged with one sign and retardation in the electroscope charged with the other, but the total number of individual observations in favour of retardation was only 52, against 28 in favour of acceleration.

Comparison of the results obtained with the inorganic constituents of bones from non-malignant and those from malignant cases affords confirmatory evidence of the influence of carcinoma upon the electrical properties of the tissues, but here the natural influence of the inorganic constituents appears to be accelerative, and in carcinoma the tendency is increased. Thus two out of four samples of inorganic constituents of bone from non-malignant cases afforded discordant results showing acceleration in the electroscope charged with one sign and retardation in the other, while the total number of individual observations in favour of acceleration was 41 against 29 for retardation, whereas when derived from cases of carcinoma the discordancy was somewhat less and the total number of individual observations in favour of acceleration was 53, against 27 for retardation.

Leaving on one side the evidence afforded by electrical examination of kidney and spleen on the ground that the results are not sufficiently clear to allow of deductions being drawn, I pass to the consideration of substances commonly supposed to be causally related to carcinoma. In this part of the subject the evidence that I have to offer is of different value in different cases. Electrical examination of clay pipe, of paraffin wax, and of cholesterin gall-stone has been carried out on so many occasions that I have more confidence in the case of these substances than in that of others of which the electroscopic examinations are clearly too few. Here I can only beg your indulgence and plead the motto of our College as an excuse (ὁ βίος βραχὺς ἡ δε τέχνη μακρή).

I have already stated that I find evidence that clay pipes exert an accelerating influence upon electroscopic leak, whether the gold leaves be charged − or +. In the case of paraffin and cholesterin gall-stone the evidence is no less clear, but both substances exert a retarding influence; and, again, whether the electrical charge on the leaves be − or +. Experiments with different samples of pitch seem to show, on the whole, that this substance exerts a retarding influence, but there is no reason to suppose that a uniform effect would be produced by all samples of this or of any other substance of an impure or complex nature. The same criticism holds good in the case of soot, one sample of which yielded me evidence of retardation, while the other gave uncertain results. Metallic arsenic, arsenious oxide, and areca nut appeared to be without effect upon electroscopic leak, but too few experiments were made with them to allow me to speak with confidence.

In my experiments with the substances mentioned above—some of the earliest made in the entire research—I sought to show that the accelerating or retarding property was manifested even though the substance under examination were covered with an aluminium cap. In numerous instances this appeared to be the case, and undoubtedly, if true, it would afford convincing proof of the similarity of the action of the substances with that of recognised radio-active substances. But owing to the fact that I have found an aluminium disc to become electrically modified by the proximity of a recognised radio-active substance or of a pure cholesterin gall-stone, my conclusions on this point require reconsideration. It may be added, however, that even if the influence from the substances did not traverse the aluminium it would not disprove the possibility of their being essentially "radio-active," since conceivably they might only give off α particles, or α particles and β radiations of so low a penetrating power that they failed to traverse the aluminium screen.

Having described in brief the electrical effects of the various substances that particularly interest us from a medical point of view, it is now necessary to revert to the recognised radio-active substances.

I have already said that I have reason to believe that recognised radio-active substances induce "anti-radio-activity" in an aluminium disc with which they have been placed in proximity, though not in contact, for a certain length of time. This change, I believe, is indicated by the acquisition of a retarding power by the disc on electroscopic leak. But there is no doubt that a metallic surface that has been bombarded by radio-active rays manifests physical change of a gross kind. Thus, the anticathode of an x ray tube not infrequently becomes perforated in course of time; an aluminium disc which has been exposed to radium for four months shows actual pits on its surface; while an aluminium disc exposed to the relatively feeble radio-activity of uranium for four months shows a loss of polish of its surface over an area corresponding to that which had been in proximity to the uranium. In the last lecture it will be shown that animal cells in like manner afford evidence of altered behaviour as the result of proximity to recognised radio-active substances.

This brings us to a consideration of *extreme* importance. There is no doubt that the facts and the conclusions of the chemist and physicist cannot be applied to biological problems in a crude manner. It is unnecessary to labour this point. It is supported by the whole of chemical physiology and pathology, from so simple an e: fact that iron in combination with globulin i hæmoglobin fails to give the ordinary chemical tests for inorganic iron to the complicated problems of immunity which have shown repeatedly that the animal body is not a mere test tube in which a simple chemical process is taking place. In a word, for the biologist a necessary preliminary to a consideration of radio-activity as understood by the chemist and physicist is a determination whether the radio-active element when in combination with protein behaves in the same way as it does when in combination with other elements to form an "inorganic" compound. It is in the latter form alone that it has been examined by chemist and physicist.

---

[12] Ibid., p. 127.

Even if a series of inorganic compounds of a radio-active element be examined it will be found that the radio-activity as measured by the rate of leak of an electroscope is not identical for all of them. Thus Colwell and I have shown that the rate of leak of an electroscope in which are examined a number of uranates of the alkalies and alkaline earths as well as the nitrate and sulphates of uranium varies inversely as the atomic weight and the valency of the elements with which the uranium is linked. From this we argued that uranium in combination with the huge protein molecule would show a correspondingly enormous diminution of its influence on electroscopic leak.[13] This proved to be the case. We showed, further, that the radio-activity of the uranium is not lost, but only masked, for the ash of an incinerated albuminous compound of uranium or of such inorganic compounds as the nitrate and sulphates of uranium or ammonium uranate (which are more or less completely disintegrated on incineration with the formation of an ash consisting chiefly or entirely of an oxide of uranium) produces a profound acceleration of leak. Similar results were obtained with the nitrate and sulphate of thorium and a thorium albuminous compound. Full details will be found in the original paper. Below are given examples in illustration of the statements made above:—

Mean Values of Electroscopic Leak in the Presence of Certain Uranium and Thorium Compounds in the Natural State and After Incineration.

—	Mean rate of leak per hour in millimetres.	
	Natural state.	Incinerated.
Black uranium oxide	175	177
Ammonium uranate	125	171
Thallium uranate	101	114
Uranyl sulphate	91	177
Uranyl nitrate	80	187
Uranous sulphate	62	159
Uranium-Witte peptone	22 4	126
Uranium serum (pleural fluid) ..	13 5	85
Uranium-egg-white	13	95
Uranium-spleen-pulp	10 9	53 6
Thorium sulphate	62	124
Thorium nitrate	55	142
Thorium egg-white	7 5	41 4

Natural leak of empty electroscope 3 6 millimetres per hour.

Now the uranium and thorium albuminous compounds contained about 10 per cent. of the radio-active element by weight, and it has a ... effect is small and ... they be allowed to ... air, while at least the thorium compound fails to affect the film through a screen so thin as that formed by brushing egg-white over tissue paper. Evidence of radio-activity in the physical sense is, therefore, reduced to a very low point, and it is easily conceivable that with smaller percentages of the radio-active element, or in combination with still larger molecules or combinations of molecules, all evidence of "radio-activity" should be lost, although the fact that the substance in question contains the recognised radio-active element would be immediately demonstrable on removing the impeding constituents of the compound by incineration.

Proceeding on these lines, I have incinerated animal chemists, but without success. Clearly the tissues contain no radio-active substance which can survive exposure to a white heat. Whether they contain a radio active substance that can withstand a temperature of 300° C., after which skotographic action disappears, but is dissipated or disintegrated between 300° C. and the temperature of white heat, it is impossible to say. In any case experiments with albuminous compounds of recognised radio active substances, such as uranium and thorium, indicate that small evidence of radio-activity manifested by an animal tissue does not necessarily mean that that tissue contains only a small amount of a radio-active element. The smallness of the evidence may simply depend upon the relative completeness with which the radio-activity is masked by the albuminous molecules with which the radio-active element is in combination.

By comparing the rates of electroscopic leak when the substance is directly exposed to the charged leaves and when it is separated from them by a screen of thin aluminium foil it is possible to separate that portion of the leak which is due to the impact of α particles from that portion due to β and γ rays. As is shown by the following table, the masked radio-activity consists chiefly, if not entirely, of α particles. In the case of thorium compounds the table is of particular importance, inasmuch as it not only shows the great increase of leak due to α particles after incineration but also an enormous disappearance of some radio-active element producing β and γ rays during incineration. It is necessary to add that the amount of radio-activity that is removed from thorium compounds by incineration varies considerably under a number of circumstances that need not be mentioned here, but that all the thorium compounds given in the table were prepared from a single sample of thorium and are comparable amongst themselves, though not with those given in the preceding table.

Portions of the Rate of Leak per Hour occasioned by Certain Uranium and Thorium Compounds due to α Particles and to β + γ Radiations.

—	Natural state.		Incinerated	
	α particles	β + γ rays	α particles	β + γ rays.
Black uranium oxide	145 8	29 2	144 0	33 0
Ammonium uranate	101·2	23 8	145 5	25 5

As to the work done and the changes produced within the molecule by the imprisoned α particles it is only possible ... Evidence has been given that ... ency to accelerate electro- ... conditions of the tissue in ... that the bombardment with ... minium disc in proximity with a recognised radio-active substance may lead to that "anti-radio-activity" of the disc which I have described.

LECTURE IV.

INFLUENCE OF RECOGNISED RADIO-ACTIVITY AND OF NON-MALIGNANT MATERIAL UPON THE DIVISION OF ANIMAL CELLS. SUMMARY OF RESULTS. THE RELATION OF RADIO-ACTIVITY TO CARCINOMA.

Hitherto the experiments which I have described have been of a chemical or a physical nature; the next step, and the last I am at the present time in a position to make, will be into the animal kingdom. Whatever the results we may have obtained, their sole importance to us as biologists, and even more as medical men, lies in any application they may have to the processes going on in the animal cell. If radio-activity, if the peculiar skotographic and electrical properties we have now found to be associated with a number of substances, some of which are derived from the animal body, influence cell-nutrition, cell-growth, cell-multiplication, they are of interest to us; if not, we may leave them on one side.

---

[13] Ibid., p. 156.

The cell which I have chosen for this part of the research is the ovum of ascaris megalocephala, an intestinal entozoon of the horse. When removed from the oviduct the ovum shows a thick cell membrane, a single undivided cell, and a general absence of pigment or food-stuffs. Since it is obtainable in enormous numbers, is clearly visible with a half-inch objective, and passes through the changes up to the formation of a complete living and moving embryo worm within a few days or a few weeks according to the temperature at which development is allowed to proceed, it is very suitable to our purpose. Examination of the development of the ovum when it has been exposed to the influence of recognised radio-activity has been carried out in the case of x rays, radium, thorium, and uranium.[14] The results agree remarkably, not only in their general direction, but also in the fact that certain special effects are produced by the two most potent members of the group, radium and x rays.

The experiments consisted in determining the rates of division of the cells under conditions that differed only in respect of their exposure or non-exposure to radio-activity. In the case of x rays, exposure lasted varying times from two minutes to 20 minutes, and the ova were exposed to the rays at the commencement of the experiment when they were all in the one-cell stage. In the case of radium, thorium, and uranium the ova were exposed to the action of the substance during the whole time of their development. Inasmuch as x rays are γ rays alone, while radium, thorium, and uranium give off α particles as well as β and γ rays, the experiments differed in this respect. Moreover, since the radium, thorium, and uranium were exposed to the ova without any intervening substance except a thin layer of air, the cells were acted on by all three constituents of radio-activity in the case of these substances. Below are given the results of an experiment using x rays:—

Characters of Cell Division in 200 Ova after Exposure to X Rays for Varying Periods.

Immediately after Exposure.
All cells in 1-cell stage.

24 Hours after Exposure (Room Temperature).

—	1 cell stage.	2 cell stage.
Control	158	43
2 minutes' exposure	140	60
4 ,, ,, ...	151	49
6 ,, ,, ...	164	36
9 ,, ,, ...	175	25
12 ,, ,, ...	184	16
15 ,, ,, ...	187	13
20 ,, ,, ...	194	6

48 Hours after Exposure (Room Temperature).

—	1 cell stage.	2-cell stage.	3 cell stage	4-cell stage.
Control	74	65	26	35
2 minutes' exposure	71	52	22	55
4 ,, ,, ...	81	42	21	56
6 ,, ,, ...	90	46	20	44

12 ,, ,, ...	104	60	15	21
15 ,, ,, ...	128	43	14	15
20 ,, ,, ...	126	57	13	14

This experiment, which has been repeated on many occasions with similar results, shows conclusively that x rays have a dual effect. Short exposures accelerate, long exposures retard cell division.

Since the ovum does not increase in size during development it becomes impossible to conduct the experiment satisfactorily during the period between the 4-cell stage and the early embryo, but with the formation of the embryo the accelerating and the retarding influences of the x rays again become manifest. Thus the ova concerning which details have been given above were transferred to the incubator at 37° C. during the third and fourth days after exposure to x rays, and it was then found that the control specimen showed immature embryos and one living and moving worm; the 2-minute and 4-minute specimens were indistinguishable from the control and also showed one living and moving worm apiece. But in the 6-minute specimen there were three living worms, in the 9-minute specimen six, in the 12-minute specimen one, in the 15-minute specimen two, and in the 20-minute specimen there were 21 living and moving worms. Here we have evidence of accelerated development. Evidence of the antagonistic influence of the rays on the same specimens of ova was obtained by keeping them in the incubator for a further period of three days, by which time development has proceeded to its furthest extent within the egg case. Below are given the final results:—

—	Complete development.	Failure of development.

Movement and Absence of Movement in 50 Completely Developed Embryos.

—	Living and moving.	Motionless.
Control	45	5
20 minutes' exposure	30	20

The antagonistic influence of x rays upon the development of the ova of ascaris megalocephala has already been described by Perthes,[15] and Bonney and I fully confirm his results both with regard to the main proposition and with regard to the observation that though division of the cells may go on for a certain length of time exposure to x rays in large doses leads to the formation of monstrosities and abortive embryos. Perthes, however, failed to recognise an accelerating influence. Working with the root-tips of plants, Cattley[16] has obtained results similar to those of Bonney and myself both as regards acceleration and as regards retardation of cell division, but he found no evidence of gross pathological change at any time.

Exposure of ova to radium leads to results practically identical with those following exposure to x rays. For the first 24 hours of the experiment division occurs more rapidly in the cells exposed to radium than in the control, but from that time forward division in the control comes to the front, and at the conclusion of the experiment the control contains a larger number of living and moving worms than the sample exposed to radium. Nevertheless, as in the x-ray experiment, the first fully developed and living worms are met with not in the control but in the irradiated specimen. Finally, the specimen exposed to radium shows ova in all stages of development, in some of which the division appears to have proceeded on normal lines previous to its arrest, while in many it has been irregular, as shown by abnormality of the number of cells to which division has given rise, and a wide irregularity in size of the daughter cells. (Fig. 14.)

As might be expected, exposure of ova to uranium or thorium leads to less marked results than exposure to x rays or radium. In particular there is no evidence of the production of monstrosities, nor is there any recognisable difference in the number of ova that arrive at the formation of living worms. On the other hand, acceleration of division in the early stages and retardation in the later are shown with clearness. *The following experiment illustrates these* points:—

Control	115	85
Thoria exposed	42	158
Uranium-exposed	81	119

11/10/08. All specimens consisted of fully-developed living worms.

Examination into the effect upon cell division of exposure of the ova to other substances (a layer of air intervening) is being carried out at the present time in my laboratory by Somerville Hastings and myself. In a preliminary communication[17] we record the results of experiments with materials of *importance in connexion with the subject now* under discussion. Thus we have examined the effect of exposing ova to various extracts of tissues having skotographic power, and find marked evidence that the rate of development is influenced by the character of the extract in *proximity with which they are dividing. Thus the proximity* of a protein-free watery extract of sheep's liver or of ovary of herring causes the ova to pass from the one-cell stage to the two-cell stage more slowly than in the control—i.e., retards development—while a similar extract of the testis of the herring accelerates division. Quite apart from the results to which this remarkable observation may possibly give rise in the future, it is clear that the effects of these extracts, acting on the cell, as they do, through the egg case, and producing results similar to those which follow exposure of the ova to the action of x rays and radio-active substances in general, suggest that there resides in animal tissues *a force unrecognised hitherto and resembling radio-*activity in certain respects.

I have now laid before you the results which I have so far obtained in this research. I have not hesitated to occupy the greater part of the time at my disposal in this way, partly because in cancer *research there is at present more* need for practical experiment than for theoretical disquisition, and partly because the Croonian lectures afford a rare opportunity for presenting the results of a prolonged research in an orderly manner. It is right, however, that in the time remaining to me I should summarise my results, and, as far as may be, c[illegible] with carcinoma under [illegible]

The original question with which [illegible] viz., Do the physical agents which are commonly supposed to give rise to cancer (clay pipes, soot, &c.), and do samples of carcinomatous material afford evidence of the possession of radio-active properties?—*is not conclusively answered.** In certain respects they behave like the radio-active materials of the chemist or physicist, but in no single instance do they respond to all the criteria of recognised radio-activity. *Thus* I have shown that many of the substances affect a photographic plate *in the dark*, but, on the *other* hand, few can act on the plate if a screen be interposed; and even in those instances in which a positive result is obtained under these circumstances it is doubtful whether the interposed *celloidin* screen is fairly so-called. Nevertheless, it is doubtful whether the *power of acting through a screen* is a necessary criterion of radio-activity, since I have shown that albuminous compounds of recognised radio-active substances may possess a *power of acting* on the photographic plate which will not traverse an extremely thin screen, and, indeed, may be devoid of photographic powers altogether. In the latter *respect they* are comparable with clay pipe, inasmuch as neither type of substance acts on a photographic plate and both accelerate the discharge of an electroscope; in the same category comes carcinoma material which has been extracted with acetone or with water and subsequently *with ether. Possibly, too,* some specimens of spleen and of the inorganic constituents of bone are to be reckoned in the same class.

Even a greater difficulty arises in connexion with those substances which I have found to retard electroscopic leak. Such a *property is entirely* repugnant to present ideas of radio-activity. If I am correct in asserting that evidence of retardation can be obtained by the use of recognised radio-active substances (as in the case of aluminium discs, which have been placed in proximity to uranium, thorium, or pitchblende) this difficulty is overcome. It may be that the dual accelerative and retarding influence which I have found all forms of radio-activity to *exert upon the development* of the ova of ascaris megalocephala will help in determining this important question. Already this line of research is indicating that certain animal extracts having skotographic powers resembling those of radio-active substances up to a *certain point are able to influence the rate of development of* animal cells when acting on them from a distance and through the screen of their own egg-case. It is not impossible that we shall find that the laws of radio-activity as determined by the physicist require some modification when adopted *into biology* owing to *the* presence of *the* protein molecule, just as the laws of filtration and osmosis have required adjusting to the special circumstances of the case. I showed some years ago that the presence of even a minute trace of protein profoundly modifies the rate of osmosis,[18] and I showed in the last lecture that combination of a radio-active element with a protein molecule profoundly modifies the rate with which it induces electroscopic leak and its photographic powers.

Below are given in tabular form the chief photographic and electroscopic results hitherto obtained.

T[illegible] photographic plate [illegible] s electroscopic [illegible]

Rec[illegible] stances.	[illegible] m, thorium, uranium albuminate some weeks after its preparation.
Other substances of research.	No member found.

Type of properties. The substance acts on a photographic plate [illegible] *Accelerates* electroscopic leak [illegible] es be + or −. [illegible]

[illegible] stances.	
Other substances of research.	

Type of properties. The substance acts on a photographic plate directly and *also* through a screen. It *retards* electroscopic leak *whether the charge on* the gold leaves be + or −.

Recognised radio-active substances.	No member of the group found.
Other substances of research.	Solid mass of hepatic material.

Type of properties. The substance acts on a photographic plate directly, but *not* through, a screen. It *retards* electroscopic leak whether the charge on the gold leaves be + or −.

Recognised radio-active substances.	No member of the group found.
Other substances of research.	Carcinoma extract, watery or [illegible]

Type of properties. The substance has *no* photographic action whatever. It *accelerates* electroscopic leak whether the charge on the leaves *be + or −.*

Recognised radio-active substance.	Thorium (?) and certain specimens of uranium albuminates directly [illegible]
Other substances of research.	

Type of properties. The substance has *no* photographic action whatever. It *retards* electroscopic leak whether the charge on the leaves be + or −.

Substance prepared *by means of* recognised radio-active substance.	*Aluminium* discs after proximity to uranium or thorium.
Other substances *of* research.	[illegible] after proximity [illegible]

[18] Journal of Physiology, vol. xix., 18[illegible], p. 1[illegible].

Leaving now the question whether the substances commonly supposed to be causally related to cancer and certain animal tissues, including carcinomatous material, are radio-active as unanswered, and, in our present state of knowledge, as unanswerable, we may pass to consider recognised facts in connexion with carcinoma as a disease in the light of the experimental evidence I have adduced. It is impossible for me to traverse the whole field, partly from lack of time, partly because I *should thereby* introduce too much contentious matter. I shall therefore confine myself to a few salient points, offering you something in the nature of an impressionist picture.

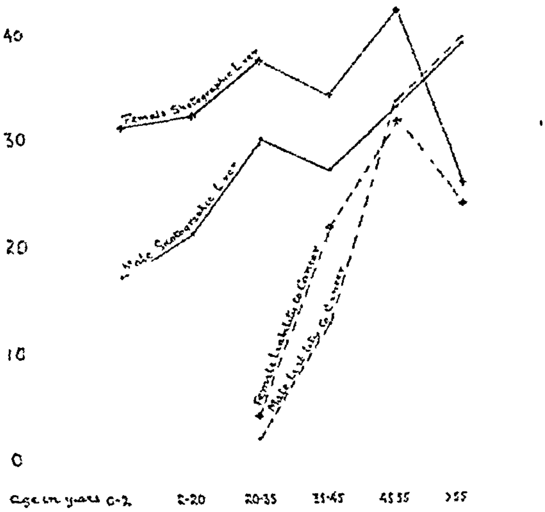
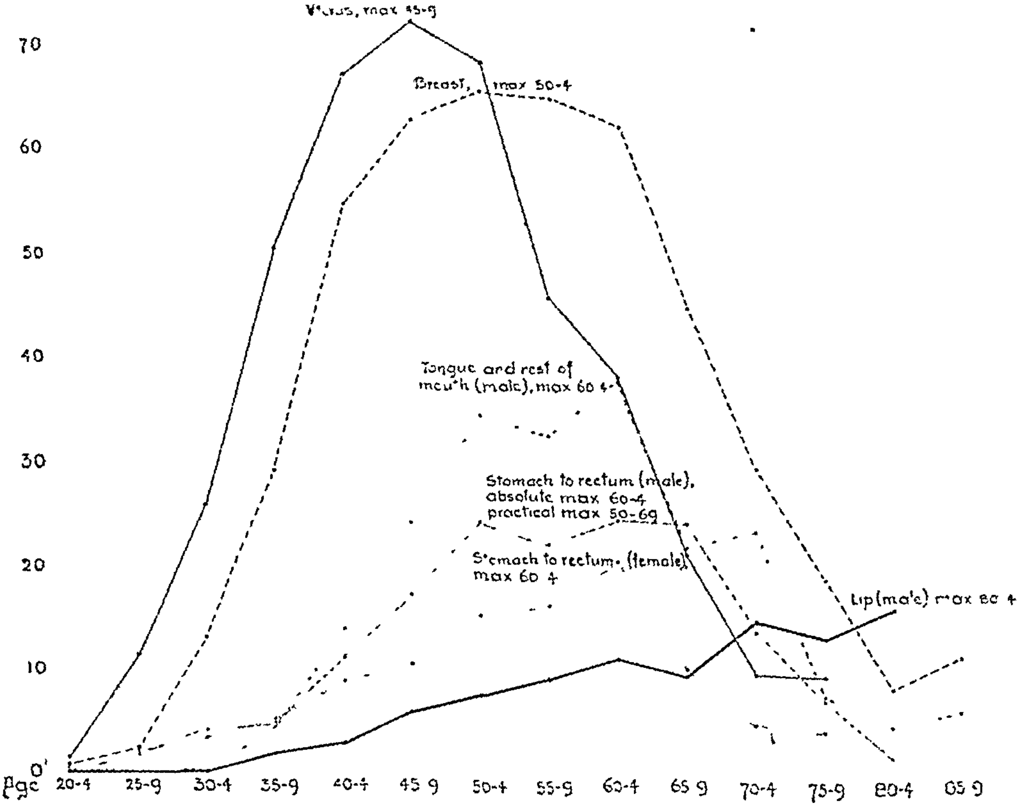
complete

FIG. 15.



Liability to carcinoma of different sexes.

FIG. 16.



Liability to carcinoma at different age periods.

One of the most certain features of carcinoma (at all events as we meet with it in this country) is that it occurs more commonly in women than in men, and that the case-incidence, corrected by the number of persons of the sex living at various ages, in both sexes runs on parallel ascending lines up to the age of about 55 years, while after that age the lines diverge, liability to the disease continuing to increase in males, but undergoing a sharp diminution in females. It is certainly remarkable that the degree of skotographic power of the liver in the two sexes and at different age-periods affords a pair of curves, agreeing absolutely in these points with the curves of cancer liability (cf. *Fig.* 15). It is possible that the identity of the two *pairs* of curves is a coincidence, and that both cancerous and skotographic conditions may depend upon some common underlying *cause—e g., senility.* Thus, curves made for the incidence of fibrotic kidney and greyness of hair would probably run parallel courses, but no one would infer that the one bears a causal relation to the other. But when one finds that the liability of liver, kidney, lung, and spleen to primary and, in the main, to secondary growths varies directly with their skotographic power, that the liability of gall-bladder, urinary bladder, and kidney to carcinoma varies directly with the skotographic value of the calculi by which severally they are affected, that carcinomatous material possesses this skotographic power, practically without exception, and that the normal skotographic power of a tissue is modified by the presence in it of a carcinomatous mass, the idea that the two are in some way interdependent is strengthened. And when one further finds that these tissues or their extracts are capable of influencing the rate of division of animal cells, the suggestion that in them lies the key of a disease which is, after all, nothing more than a disorderly overgrowth of a particular variety of cell becomes alluring. Nor is the fact that certain of the extracts have been found to possess accelerative, while others possess retarding, powers on development a difficulty, for it is clear that for the occurrence of carcinoma it is as necessary for the subjacent tissues to undergo a diminution of their normal resisting powers to the encroachment of the epithelial cells as for these latter to undergo an increase in their normal rate of reproduction.

This brings us to the question of metastases. I have long felt that the metastases in carcinoma are not regarded in their proper light. Stripped of non-essentials, the occurrence of a metastasis simply means that a cell which is capable [illegible] which it is not killed. [illegible] carcinomatous cell is [illegible] tion, or other means [illegible] ning the occurrence or non-occurrence of a metastasis as the transported carcinoma cell. This is shown by the great variations in regard to metastasis met with even in carcinoma of a single site. We cannot believe that a fundamental difference obtains between the cells of one carcinoma of the cervix uteri and those of another, either as regard their "malignancy" or their liability to transport to the lymphatic glands, liver, &c. And yet, as a reference to statistics collected at the Middlesex Hospital will show, more than half of the necropsies on cases dying from carcinoma of the cervix reveal an entire absence of metastasis.[19] The only reasonable explanation of this fact is that carcinoma cells are disseminated through the body in all cases, but in half of them they are destroyed at the seat of their lodgment.

In what the difference between a tissue which allows a transported carcinoma cell to grow and multiply and a tissue which destroys it consists, it is impossible to say, but the different properties of tissue-extracts upon the division of the [illegible] that in them may [illegible] Nevertheless, the [illegible] a body affects the [illegible] tient, even though [illegible] indicates that an [illegible] the initial cause of the carcinoma, upon distant parts. And in this connexion one may ask whether it is not possible that those rare cases may be thus explained in which death in carcinoma cannot be attributed with fairness either to the mass of growth, septic absorption, mechanical interference with vital parts, or other similar cause. One of the most noteworthy points in connexion with carcinoma is that a mass will kill, being carcinoma, which would probably not kill if, *ceteris paribus*, it were inflammatory. It is only necessary to compare the certain death from so small a mass of disease as is often a carcinoma of the body of the uterus, with the relatively good prognosis of a far more extensive tuberculosis, actinomycosis, or tertiary syphilitic condition.

If the general liability to carcinoma in males and females be split up into its component parts and the liability to carcinoma at different sites be considered individually, certain interesting points are disclosed. This has been done for 6421 cases of cancer at the Middlesex Hospital of which details as to age are available. The cases are distributed as follows: Uterus, 2205 cases; breast, 2126 cases; alimentary tract from stomach to rectum, 470 female and 586 male cases; tongue and rest of mouth, 783 cases (male); lip, 251 cases (male). The total number of cases of each kind in each quinquennial age-period has been corrected for the number of persons (male or female as the case may be) surviving at [illegible] that ag[illegible] formed [illegible] Fig. 16.

The most striking point in the curves is that whereas all of them show a rising [illegible] creasing liability [illegible] of cancer of the [illegible] reached, after whi[illegible] more or less sudde[illegible] to cancer of a special organ does not occur at the same age as the maximum liability to cancer of another organ, nor are the ascents and descents of the different curves equally rapid or high in all cases.

There is thus a great contrast between cancer of the lip and cancer of the uterus, for example, so far as the liability of individuals to the two [illegible] difference may clearly [illegible] incidence of the cause [illegible] tissue upon which the cause is acting. So far as a difference in the tissue is concerned, there is no doubt that the maximal liability to cancer of the uterus occurs about the menopause and that it diminishes with great rapidity immediately after. But the uterine, and particularly the cervical, changes following the menopause are amongst the least marked of climacteric changes, and in any case are minute compared with the [illegible] egnancy. If, however, [illegible] nt of view of a differen[illegible] cause of the disease the matter becomes simpler.

The cervix uteri is particularly suitable for an inquiry into the etiology of carcinoma. It is a limited region; it is in the majority of cases affected by the simplest form of [illegible] while the third, laceration during childbirth, is merely a trauma more or less resembling traumata in other regions, and, once occasioned, persists throughout life. At the same time, as it is more than usually protected from outside influences, it is one of the commonest, if not actually the commonest seat of carcinoma. Of these three conditions, the two that are peculiar to the cervix are those which attract most attention when considered in relation to the age for the maximum liability to carcinoma of the cervix, partly because traumata occur in other regions, partly because a period of many years usually elapses between the last parturition and the age of maximum liability. And considering menstrual blood and seminal fluid as possibly containing the essential cause of carcinoma of the cervix, menstrual blood must be put on one side, if only for the reason that if it were the cause one would expect that vagina and vulva and body of the uterus would not show so marked an inferiority in liability to carcinoma as they undoubtedly do. This leaves the seminal fluid, and it is a remarkable fact in this connexion that the spermatozoon is the most potent instigator of cell division known when it acts upon a specific cell, the ovum, and that an extract of the testis of the herring (which consists almost entirely of spermatozoa) favours the division of the cells of the ova of ascaris megalocephala to an extraordinary extent, and at the same time possesses marked skotographic powers (Fig. 17).[20]

In the case of the breast, it appears to me that the observation of MacCormac that various bacteria possess skotographic powers is of great importance in conjunction with the fact that a greater or less degree of chronic mastitis is so commonly met with in mammary carcinoma. From this point of view mammary carcinoma may be brought into line with carcinomata arising on old cicatrices and long-standing ulcers, whether these be simple or lupoid. It is, indeed, remarkable that the only varieties of bacteria which have been fo[illegible] those which [illegible] phylococci, [illegible] ongst the animal kingdom is so much more commonly affected by carcinoma that it may be termed a pre-eminently human disease. When it is remembered that bacteria—especially pyogenetic and tuberculous bacteria—may remain latent for years; when it is remembered that the skotographic action, if not of bacteria at least of other animal substances, may persist for a period, certainly of months and probably of years, the question arises whether we shall not find the essential cause of carcinoma affecting mamma, cicatrices, old ulcers, directly connected with the bacteria underlying the primary chronic inflammatory condition. If this be so, if the bacteria introduced into the breast, possibly during some lactation period, carry with them by virtue of their skotographic power the cause of a carcinoma which develops years later, we should expect the feebly skotographic bacteria to induce carcinoma later in the individual's life than the far more powerful spermatozoa, we should expect the period of maximal liability to a carcinoma of bacterial origin to be spread over a larger range of years than one of spermatozoal origin, we should expect a later onset of diminution in liability with a carcinoma of bacterial origin than with one of spermatozoal origin, but in both cases we should expect the liability to cancer to diminish in later life. In a word, we should expect to find carcinoma of the breast and carcinoma of the cervix showing just those differences of incidence which they actually manifest.

[20] [illegible] animals from carcinoma cervicis. I suggest [illegible]

But if, in the case of the uterus, it is difficult to associate the occurrence of carcinoma with peculiarities on the part of the tissue itself, this is even more difficult in the case of carcinoma affecting that part of the alimentary tract lying between stomach and rectum. A glance at the curves of liability to cancer in these regions drawn up for males and for females shows that in males the liability is not only greater but also that it reaches a maximum some ten years earlier than in females and persists at that maximum for five years longer. We cannot consider that there is so striking a difference between male and female alimentary tissues as this would indicate in the absence of definite evidence on the point. It is easier to imagine that some factor leading to increased division of epithelial cells is more potent in males than in females during the age-period 50 to 69. It would serve no good purpose to discuss here what that factor may be, but it may be pointed out that Sir J. J. Thomson has shown that certain food-stuffs, notably wheaten flour, may be radio-active, while I have shown above that many animal substances have properties which may be radio-active, that both definitely recognised radio-active substances and extracts of animal tissues are able to accelerate cell-division in the ova of ascaris, and that, partly as a result of the greater degree to which they are occupied in arduous labour, men consume more food than women.

I have left consideration of the curves obtained for carcinoma of the lip and of the tongue and other parts of the mouth to the last because of their great dissimilarity, in spite of the similarity of the tissues concerned and of the identity of most of the conditions to which those tissues are subjected. This dissimilarity of the curves of liability to carcinoma, and particularly the fact that the liability to carcinoma of the lip undergoes no diminution in old age such as is observed in the case of carcinoma in all other sites that we have examined, is strong evidence that some fundamentally different condition obtains in the two situations. The persistency with which the old man clings to his pipe, holding it between his lips whether actually smoking or not, whether awake or dozing, as he sits in the sun or by the fireside, is as characteristic of the ages above 70 as is the toothless condition which commences to set in about 65. On the assumption that the pipe in some way is directly related to carcinoma of the lip while the teeth are in some way directly related to carcinoma of the tongue and other parts of the mouth, the curves of liability to this disease in the two situations should be exactly as we find them to be.

It may be urged that the observations I have brought forward are nothing more than evidences of that "chronic irritation" which since the time of Virchow has been held to play an important part in the causation of carcinoma. To this my answer must be that the term "chronic irritation" is meaningless and only indicates that some common factor exists in a variety of conditions that differ otherwise to the greatest extent. Is [illegible] not possible that the common factor, which must be capable [illegible] stimulating the growth of certain cells while it depresses the growth of others, which must reside in substances of the widest diversity, which must act with varying intensities in different cases though always with comparative slowness, the natural action of which must be progressive so long as it persists, should be radio-activity? The x rays cause carcinoma, they stimulate (like other radio-active substances) the growth of cells, and again they retard the growth of cells; carcinomatous material, non-carcinomatous material, extracts of animal tissues, various substances usually regarded as causally related to carcinoma, possess properties resembling those of recognised radio-active substances to a greater or less degree when considered from the physicist's point of view, and there is evidence that they possess powers of stimulating or depressing the division of animal cells. Such similarities are at least suggestive.

At the same time as radio-activity, using that term to cover the properties of other than *recognised* radio-active substances for the moment, would serve to explain a large number of the salient features of carcinoma as a disease, it would fall in line with other facts that have been made known more recently, and often afford a common ground for views that appear, at first sight, to be diametrically opposed. It would fall in line with the observations of Farmer, Walker, and Moore on the frequent occurrence of heterotypical and irregular mitoses in malignant new growths, for all observations go to show that the ova of ascaris megalocephala divide with great irregularity when they are exposed to recognised radio-activity, and the same is true when they are exposed to the influence of any of the watery extracts of animal substances that have been mentioned above. It would fall in line with the observations that there is a deficient secretion of pepsin and trypsin in carcinoma, for Colwell and others have shown that the activity of these enzymes is largely diminished when they are exposed to radio-active influence.[21] It would fall in line with the observation that the ereptic power of the tissues in carcinoma cases is not diminished more than in other chronic diseases accompanied by wasting (Colwell[22]), for exposure to radio-activity does not affect the ereptic power of a tissue-extract in the slightest degree. It would fall in line with the fact that certain varieties of carcinoma, notably those which are superficial, are curable by radio-activity, for, as is shown by the cases of diphtheria, typhoid fever, tetanus, anthrax, rabies, and other microbic diseases, the agent producing the disease is prepotent in elaborating the remedy. It would fall in line with the fact that carcinoma is primarily a disease in which a definite variety of cell—the epithelial—is concerned, for there is evidence that radio-activity has selective powers—e.g., in its action upon the specific cells of the testicle and upon the spleen. It would fall into line with the remarkable observations of Ehrlich and Apolant and of Haaland, that in mice transplantation of one type of tumour may lead, as they believe, to the origination of another type from the tissues of the host, for the cells of a carcinomatous mass are endowed with properties resembling those of recognised radio-active substances in many respects. It would fall into line with the observations of Bonney made in my laboratory and enunciated in his Hunterian lectures before the Royal College of Surgeons of England last year, that the onset of carcinoma in any part is preceded by local histological changes of a special kind but belonging to the "inflammation" phenomena.

On the other hand, it would not be opposed to a belief in "cancer houses and localities," for there is no reason why the soils of districts or the materials of which houses are built should not differ in the degree to which they are radio-active, nor why the local radio-activity should not be in certain instances so considerable that cancer arises in successive inhabitants time after time. In a sense, the electrical department of every hospital is a "cancer house." It would not be opposed either to an infective or non-infective, a contagious or non-contagious, an animal or vegetable parasitic, a parasitic or non-parasitic, a hereditary or non-hereditary view of cancer, for it would only be concerned with the question whether the inculpated agent is radio-active or not. So far as certain bacteria possessed the properties we are considering, the carcinoma associated with them might be regarded as bacterial and infective, but the bacterial and infective properties would be accidental and non-essential. So far as the agent which leads to hereditary transmission was provided with "radio-active" properties cancer would be hereditary, but the inheritance of cancer would be accidental and non-essential. Similarly it would not be mann's theory of anaplasia, to Ribbert's theory of tissue-tension, to Adami's theory of habit of growth, for it would constitute the underlying force required by each.

---

[21] Archives of the Middlesex Hospital, vol. xiii., 1908, Seventh Cancer Report, p. 94.

[22] Ibid., vol. xv., 1909, Eighth Cancer Report, p. 96.

There remains the question whether by applying radio- [illegible] carcinoma. To this question [illegible] experiments have hitherto [illegible] posed rats and mice to the action of x rays, or to uranium, or to thorium for months; I have kept a glass tube containing radium in the abdominal cavity of a rabbit for months; I have exposed the ears of rabbits to x rays for prolonged periods and under different circumstances, but so far the only cases of carcinoma resulting from exposure to radio-activity are those which have occurred in the human subject. Yet t[illegible] experiments I have mentioned have not been witho[illegible] importance, for, as Rowntree[23] has shown, the chang[illegible] in the rat's tail, and even more those in the rabbi[illegible] ear resemble those in human x ray dermatitis, wh[illegible] there is in certain places a well-marked overgrowth [illegible] epithelial cells. In the case of the rabbit's ear, indeed, [illegible] finds that the epithelium on the under or indirectly expos[illegible] surface shows an irregular arrangement of the hypertrophi[illegible] epithelial cells which appears to be on the border li[illegible] between non-malignancy and malignancy. When we can determine that that border line shall be crossed one of the greatest steps towards a discovery of the cure for carcinoma will have been made.

Mr. President, I have finished. No one is more conscious than I of the deficiencies of these lectures. I can only plead for your leniency on the ground that the line of research is, to the best of my belief, new, and that it has not proved unprofitable. I am of the opinion that great developments may be expected, not only in respect of cancer, but also in respect of physiological and other pathological conditions if research on these lines be extended.

GASTRO-INTESTINAL CRISES FROM EFFUSION INTO THE BOWEL WALL.[1]

By G. A. SUTHERLAND, M.D. Edin., F.R.C.P. Lond.,
PHYSICIAN TO THE HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL AND TO PADDINGTON GREEN CHILDREN'S HOSPITAL.

The occurrence of unexplained hæmorrhage is more common in childhood than in adult life. Even in the earliest days of life this tendency is present. The site of the hæmorrhage is an important one in determining both the nature of the symptoms and, in many cases, the gravity of the affection. Amongst the different parts of the body which may be affected the bowel wall is of considerable importance because of the grave and alarming symptoms which may develop and the difficulties in diagnosis and treatment which may [illegible] A condition of acute abdominal [illegible] and the problem as to whether [illegible] s not called for would appear to have taxed the diagnostic powers of many. Not infrequently mistakes in diagnosis have been made, as in other forms of acute abdominal disease. In criticising some of the recorded cases it is hoped that the writer of this paper will not be regarded as assuming a superior position. Such would be untenable, for he has apparently made more mistakes in connexion with this special affection than anyone else. This is his only claim to speak on the subject.

This special type of disease is most frequently associated with the name of Henoch, who was the first to describe it clinically. Henoch's purpura is a variety of the hæmorrhagic diathesis characterised by attacks of severe abdominal pain, vomiting, and the passage of blood and mucus by the bowel. It is only because of the abdominal symptoms, on which he laid special emphasis, that it is to be distinguished from other forms of purpura hæmorrhagica. Osler[2] has described a number of such cases in a series of serous and sanguineous effusions on the ground that they manifestly proceed from the same cause, as they are found alternating in the same individual during the course of the illness. Other writers have described similar attacks as being due to angio-neurotic œdema, there being no evidence of hæmorrhage in any part of the body, but definite attacks of fleeting œdema having occurred. Clinically the abdominal symptoms may be identical, but it may often be possible to make [illegible] s history or from [illegible] body.

The [illegible] clinical and post-mortem aspects of this condition:—

Case 1.—A male child, three months old, passed a blood-stained [illegible] ly lesion found in the [illegible] stine. The last inch of [illegible] t there was an area of [illegible]

Case 2 (Mr. [illegible] case).—A [illegible] hospital with a history of violent pain [illegible] had become stercoraceous, and the [illegible] The abdomen was nearly motionless [illegible] especially in the lower part, and there was general tenderness on palpation. There was no distension, or tumour, or tenesmus. Peritonitis was diagnosed. The abdomen was opened and no evidence of gross disease was found. The greater part of the small intestine was empty, but a portion a few inches from the ileo-cæcal valve was found to be congested. The bowel here showed several small petechial hæmorrhages and some irregular patches of congestion from which [illegible] On the following day a careful search [illegible] ne small purpuric spots were [illegible] the buttocks, and on each leg. [illegible] ued and a diagnosis of Henoch's [illegible] firmed by subsequent attacks of [illegible] purpuric eruptions. Recovery [illegible]

[illegible] case).[4]—A boy, aged four years, was [illegible] abdominal pain and vomiting. The [illegible] was considered. Under chloroform [illegible]

Into the pathology of purpura hæmorrhagica and angio-neurotic œdema we need not enter here, but the pathological changes which have been found in the bowel wall during life and after death afford an explanation of the clinical symptoms. Hæmorrhage may take place into the mucous layer, the submucous layer, the muscular layer, or the peritoneal coat. It is probably only when considerable effusion has taken place into the tissues of the bowel wall generally that severe symptoms are produced. The hæmorrhage, if of sufficient extent, produces paralysis in the part of the bowel affected. On examination the bowel wall will be found to be deeply congested or hæmorrhagic in appearance. It is thickened and has a tough leathery feel. Scattered purpuric spots may be found on the peritoneal coat or in the mucous layer of the bowel. At a necropsy one may find many superficial ulcers on the internal surface due to sloughing at the [illegible] In other cases there may be [illegible] due to profuse hæmorrhage into the wall [illegible] ge areas of the mucous and submucous tissues.

The clinical symptoms in connexion with effusion into the bowel wall are vomiting, pain, and the passage of blood and mucus. Constipation is usually present, but in some cases

[4] Ibid., 1904, p. 96.

diarrhœa of a severe type is a marked symptom. In the milder cases the attacks are short but tend to recur. It is to be noted that hæmorrhage into the lumen of the bowel does not of itself produce any pain, so that the onset of pain at once suggests effusion into the bowel wall. The pain is of the nature of colic and is intermittent. It may be so severe that the patient rolls about in agony or is thrown into a state of opisthotonos. Pressure on the abdomen either with the hand or by lying on the face seems sometimes to afford relief. In the case of infants violent screaming occurs during the attacks of pain. The site of the abdominal pain varies in different cases. Abdominal tenderness is not usually present, but some cases are recorded in which it was a marked feature. Such attacks are acute enough and call for the administration of opiates, but between the spasms of pain the patient's appearance is satisfactory. Another stage is reached when the condition becomes one of intestinal obstruction, partial or complete; the whole aspect of the patient changes, and one recognises the typical appearance of acute abdominal disease. The nature and cause of the pain have been explained in various ways. If, however, one considers the nature of the pain, which is griping, spasmodic, and intermittent, and the usual accompaniment, obstinate constipation, it appears most natural to assume that there is paralysis of the affected part of the bowel with over-action and spasmodic contraction of the bowel wall above. The increased peristalsis is an attempt to overcome what is practically a local obstruction and pain results. A sudden attack of violent abdominal pain may be the first sign of illness, and may simulate very closely the onset of acute intussusception. Vomiting usually comes on at the onset of an abdominal attack or follows soon after. It may become so marked that everything swallowed is promptly rejected. Vomiting of blood may take place and is a valuable aid in the diagnosis as suggesting the hæmorrhagic nature of the abdominal lesion. Blood and mucus are usually passed per anum in hæmorrhagic cases. The amount of blood varies from a mere tingeing of the mucus to six or eight ounces. The patient may be rendered anæmic by the profuse intestinal hæmorrhage. At the same time blood is not necessarily present, even in hæmorrhagic cases, as the effusion may be confined entirely to the wall of the intestine. In cases of pure serous effusion there will not, of course, be any blood passed per anum. The abdomen is usually retracted in the early stages and milder cases, but with the increase of symptoms of obstruction it tends to become distended.

Attacks of intestinal colic, identical in all respects with those accompanied by the passage of blood, but without melæna, are not uncommon. These may be accompanied by œdematous or urticarial swellings in other parts of the body, which are evidence in favour of effusion into the bowel wall. Mr. Alexander Don[5] has recorded the case of a boy, aged 11 years, who was seized with sickness, vomiting, and abdominal pain. There was no melæna, but there was a purpuric rash, and œdematous circumscribed swellings appeared over the back, the thigh and leg, the back of the hand, and the dorsum of the foot. Osler, in discussing the visceral manifestations of the erythema group of skin diseases, says that the colic is probably due to localised œdema of the intestinal wall. Dr. Harrington has had an opportunity of seeing this localised œdema in a case where laparotomy was performed for suspected gall-stones.

CASE 4. (Dr Harrington's case).[6]—A young woman, aged 26 years, presented symptoms of gall stones for which laparotomy was performed. The intestines were engorged with blood and so red that a mild peritonitis was at first suspected There were no hæmorrhagic areas in the intestinal walls, but at a point within a short distance of the ileo cæcal valve a cylindrical enlargement of the ileum 2½ inches long was seen, entirely surrounding the bowel and increasing its circumference to twice the ordinary size The swelling was evidently in the bowel wall, elastic to touch, and did not pit upon pressure. No other lesion was found She had a comfortable convalescence This patient had had many previous attacks of angio neurotic œdema affecting the face, hands, and feet, accompanied at times with abdominal pain.

There would appear to be a special site of election for this form of intestinal hæmorrhage—namely, the ileo-cæcal region. Out of 20 cases in this paper in which the site of hæmorrhage was determined either during life or post mortem, the effusion was marked in the ileo-cæcal region in 15 cases. The lower end of the ileum, the cæcum, and more rarely the appendix are the parts affected. It is difficult to explain the special tendency to the effusion in these parts, although the stagnation of the bowel contents about the cæcum may be a cause of local irritation and congestion. The presence of the ileo-cæcal valve may also explain the early development of symptoms of acute obstruction, as effusion and swelling in this narrowed part of the bowel will produce more disturbance than in other parts of the intestine. Certainly the clinical fact remains that in recorded cases a preponderating number show the affection specially marked in this region. It is also a well-known fact that over 70 per cent. of cases of intussusception in infants occur in the ileo-cæcal region. May it not be possible that the sudden effusion of serum or blood in the ileo cæcal region is often the unsuspected cause of an intussusception? Illustrations of the involvement of the ileo-cæcal region in intestinal effusion are supplied in the cases here recorded. The following two cases show that the vermiform appendix alone may be involved.

CASE 5 (Dr. Jacobson's case).[7]—A woman, aged 37 years, had suffered for three days from severe pains in the right side of the abdomen. When first seen the abdominal pain was very severe and tenderness was marked over the site of the appendix. She complained also of pain in the region of the gall bladder, and located a third painful point to the right of the umbilicus. On opening the abdomen the bleeding was very profuse The appendix was five inches long and presented a very red appearance. Later, upon section, it was found to present numerous areas of hæmorrhage into its substance. There was no free bleeding into the cavity of the appendix, which was distended by a mucoid discharge. The hæmorrhage was entirely interstitial. Four days after operation the patient developed a hacking cough and brought up a quantity of bright red blood. This was followed by profuse nasal hæmorrhage, and next day by an outbreak of purpura on the skin. Petechiæ appeared on the left leg above the head of the fibula and on the abdomen, while on the calves numerous ecchymoses were found At the sites of hypodermic injection free bleeding occurred. There was never any hæmatemesis or melæna. The patient eventually made a good recovery after a somewhat prolonged attack of purpura hæmorrhagica.

For the following case I am indebted to the kindness of Mr. Arthur Edmunds who has not yet published it.

CASE 6 (Mr. Arthur Edmund's case)—A boy, aged three years, was suddenly seized with acute abdominal pain and vomiting while at dinner. For the previous ten days he had had occasional attacks of "stomach ache." The vomiting was repeated six times during the day and blood was passed per anum on three occasions. On admission the same night an indefinite swelling, cylindrical in shape, was felt half way between the umbilicus and ensiform cartilage Intussusception was diagnosed and the abdomen was opened. No tumour was found, but on examining the cæcal region the appendix was found to be hæmorrhagic and was removed. The boy made a good recovery without further symptoms. On examination of the appendix the wall was found to be swollen and infiltrated with blood, involving the submucous layers, the follicles, and the muscular layers No other lesion was present.

A diagnosis of intussusception is very readily made in cases of intestinal effusion. The resemblance of the two affections may be so striking that on reading the recorded cases I am still unable to find any one point which will serve to distinguish them. The difficulty is specially marked when the intestinal effusion attacks a healthy child, produces obstructive symptoms, and is not accompanied by any effusion or hæmorrhage in other parts of the body. The following cases illustrate the difficulty in diagnosis between intussusception and effusion into the bowel wall.

CASE 7.—A male infant, aged eight months, was admitted to hospital after three days' illness characterised by vomiting, constipation (complete save for the passage of some blood and mucus), and great thirst. Vomiting had become almost continuous and abdominal distension had been increasing The abdomen was distended and resonant and nothing abnormal could be detected on palpation, combined with rectal examination A soap-and water enema was given without any result save a little blood stained mucus Crying as if from pain was present and there was a marked abdominal facies Another enema was followed by the passage of some fæcal matter, blood, and mucus The abdomen was opened and some free fluid escaped. The small intestines were distended generally. There was no intussusception or peritonitis, but the last few inches of the small intestine were deeply congested and hæmorrhagic in appearance. Above this area were some smaller patches of hæmorrhage in the bowel wall. The abdomen was closed. The symptoms of obstruction were not relieved and vomiting again recurred A very small amount of fæcal matter was passed The child sank gradually and died two days later The necropsy revealed a dark, almost black, mass in the right iliac region, which proved to be the cæcum with its walls greatly thickened by an effusion of blood. The lumen was almost entirely occluded. The mucous surface of the cæcum was of a uniform deep purple colour, and a similar appearance was present in patches in the first six inches of the colon Here the hæmorrhages were of a purpuric character.

CASE 8—A boy, aged five years, was seized with severe abdominal pain and vomiting, which continued intermittently for four days and then ceased Two days later the same symptoms recurred with greater severity and persistence The bowels had acted irregularly until the day before admission, when the motions were at first blood stained, and later only pure blood in large amount was passed. The boy looked ill

and was sul [illegible]
which he r [illegible]
abdomen was extremely distended and resistant so that an examination was impossible without an anæsthetic. Under chloroform nothing further was discovered. The rectum was empty save for some blood-stained fluid. No fæcal matter had been passed for some days. A diagnosis of intestinal obstruction, probably [illegible] and the abdomen was opened. [illegible] a part of the bowel about five inches [illegible]

[illegible]

CASE 9 (Mr. Greig's case).[8]—A boy, aged nine years, had an attack of [illegible] tenesmus being present. A few purpuric spots were present on the legs. Intussusception was diagnosed. [illegible] chloroform a small, firm, resistant tumour was felt in the righ[illegible] region, below and to the right of the umbilicus, freely moveabl[illegible] slipping about on manipulation. [illegible] was easily delivered, and was fou[illegible] [illegible] On the following [illegible] d the left eye also [illegible] to hæmorrhagic. Purpuric spots [illegible] He made a good recovery, and

[illegible]

[illegible] a mass of blood-clot surrounding the bowel, perhaps in the wall of the bowel."

CASE 11 (Dr. J. Porter Parkinson's case[10]).—Male child, aged five years, admitted with history of four days' illness characterised by severe abdominal pain, vomiting, and melæna. [illegible] measly non-purpuri[illegible] On the following d[illegible] and great [illegible] per stool. [illegible] ted and abdomen opened. [illegible] the colon, congest[illegible] peritoneal hæmor[illegible] ing continued, on [illegible] appeared over the [illegible] necropsy general [illegible] intestine 13 extr[illegible] peas, and project[illegible] About a foot fro[illegible] hæmorrhages. D[illegible] splenic flexure. [illegible] hæmorrhage into [illegible] the middle of th[illegible] collapsed and co[illegible] hæmorrhagic infarcts in the lungs.

In a recent paper Mr. Hugh Lett lays stress on the presence of a tumour as distinguishing intussusception from this affection. But even a tumour closely simulating invaginated bowel may be present, as in Mr. Greig's and Dr. Still's cases. Tenesmus, opisthotonos, and all the rarer signs of intussusception may be present in cases of hæmorrhage into the bowel wall, so that at present we do not seem to possess any reliable means of distinguishing the two affections. They present themselves as cases of intestinal obstruction, and each one must be considered in the light of all the symptoms present. Some surgeons say the indication clearly is to open the abdomen and settle by inspection. This is probably the best course to pursue in cases where a differential diagnosis is otherwise impossible, where the signs of obstruction are urgent, and where there [illegible] tendency. In the [illegible] owing to the risk of [illegible] sloughing.

The diagnosis between intussusception and intestinal effusion is further complicated by the fact that invagination may take place as the result of effusion into the bowel wall. The occurrence of intussusception may be an early or a late complication in the course of an illness characterised by [illegible] recognised and ignorance of it may lead to the overlooking of a very serious complication in this form of hæmorrhagic trouble. The following cases illustrate the occurrence of [illegible]

[illegible] vomiting and constipation. [illegible] and brought away some hard [illegible] vomiting came on. There was [illegible] cried out in attacks of pain. [illegible] intussusception with a piece [illegible] section was performed. The [illegible] a considerable quantity of [illegible] Death followed two days after the operation. There was no necropsy.

Commenting on this case Dr. Hall says the diagnosis made at first was Henoch's purpura, but he thinks this may be rejected because of the fæcal vomiting, the presence of constipation, the absence of blood and mucus from the stools, and the existence of an intussusception. As the recorded cases show, there is nothing in these signs which are opposed to a diagnosis of Henoch's purpura complicated by an intussusception.

CASE 14 (Mr. Lett's case).[12]—Male, aged three years. There was a [illegible] purpuric spots were [illegible] operation abdominal pain was complained of again, the purpuric [illegible]

Mr. Lett's case is particularly valuable because of the occurrence of a second intussusception in the course of an attack of Henoch's purpura. The first one was ileo-cæcal and was successfully treated by operation. The second was enteric and was situated ten inches from the ileo-cæcal valve. The vomiting and pain ceased immediately after the operation, the bowels acted, and the child was free from all signs of intussusception for seven days. Unfortunately, when the second intussusception occurred the child's condition was such that any further operation was out of the question. In this case Mr. Lett has brought forward the most conclusive evidence yet adduced of the causal connexion between Henoch's [illegible]

It is n[illegible] there should be a tendency [illegible] of effusion into the bowel wal[illegible] rary paralysis in the [illegible] violent peristaltic movements occur in the part of the bowel immediately above, which is driven into the flaccid bowel and an invagination is formed.

Some cases of this affection seem to lead up very readily to a diagnosis of spontaneous reduction of an intussusception. In former years I have accepted this diagnosis without hesitation, but further experience has led me to doubt whether it is justified as often as it is made. The invagination of one part of the bowel into another is a pathological condition which, when once started, tends to increase very easily as the course of the affection shows. But the reverse process, the means by which an invaginated portion of bowel can free itself, is not at all clear or easily understood. In cases which are not submitted to operation and which recover the diagnosis must be a matter of uncertainty, but the evidence of effusion into the bowel wall is in many cases at least as strong as that of the spontaneous reduction of an intussusception. The sudden onset of abdominal pain in a previously healthy infant or child, along with vomiting and the passage of blood and mucus from the bowel, certainly suggest intussusception, but the subsidence of all symptoms in from 24 to 48 hours is equally suggestive of effusion into the bowel wall. Discussing this type of case Mr. H. S. Clogg[13] writes as follows:—

> In two cases I have recently seen, both healthy babies, three and six months of age, both were reported as becoming suddenly ill, crying with pain, turning pale, and [illegible] slime by the bowel. In both [illegible] intussusception, and the aspe[illegible] The abdomen could be easily palpated and nothing was felt. So strong was the history that I examined under an anæsthetic, still with a negative result. In these two cases I could feel nothing. As both babies were a little collapsed rectal salines were given. [illegible] further blood and mucus, and in 24 hours the bal[illegible] It is hardly possible to regard such cases as coli[illegible] consider them as cases of intussusception reduced spontaneously.

CASE 15 (Dr. Still's case).[14]—Female infant, four months old. Two days previously suddenly began to scream and continued for two hours. Then vomiting and passage of blood and mucus per anum, without fæcal matter. Frequent attacks of abdominal pain. On the day she was seen the bowels had acted twice, once only blood and mucus had passed and the second time the same with a trace of green fæces. Only slight vomiting during previous 18 hours. No tumour felt. An enema of warm olive oil brought away a large quantity of mucus but no fæcal matter. The symptoms steadily diminished and recovery followed. In this case an intussusception had been carefully looked for but none found.

These three cases may be regarded as typical of a class in which a diagnosis of spontaneous reduction of an intussusception is commonly made. On the clinical evidence, however, one can only assert that there were symptoms of obstruction of the bowel with melæna; and these may equally well have been produced by effusion into the bowel wall with temporary paralysis. More precise information is gained when the abdomen is opened and the condition of the bowel can be examined. Even under such circumstances if one is inclined to a diagnosis of spontaneous reduction of an intussusception it is very easy to find confirmatory if not conclusive evidence. The condition of the bowel wall, congested or hæmorrhagic, and thickened by the effusion, is very similar to that of a mechanically reduced intussusception, and the surgeon very naturally assumes that nature has simply anticipated his procedure. In a certain number of cases the further progress of the disease will show clearly that it was quite unnecessary to assume the existence of an intussusception (see Case 8). The following case I accepted at the time as an example of the spontaneous reduction of an intussusception, but now I think it may have been simply a sudden effusion into the bowel wall.

CASE 16.—A male, aged four years. Quite well until 3 P.M. (four hours before admission), when he was suddenly seized with acute abdominal pain. Has vomited three times. Has seemed drowsy and has been having attacks of pain about every five minutes, when he rolls about in agony. Frequent desire to defæcate and straining, but nothing passed. Boy well nourished, but lies in a drowsy condition; looks collapsed, eyes sunken, slightly sick occasionally. Frequent attacks of abdominal pain in which he screams, tosses about, and presses both hands to umbilical region (to which pain is referred); then passes into a state of opisthotonos, with only back of head and heels resting on the bed. As pain subsides the opisthotonos passes off. Abdomen is soft, swollen, not generally tender. A hard tender lump, about the size of a hen's egg, is felt just above and to the right of the umbilicus, and firm pressure here elicits a paroxysm of pain. At 10 P.M. laparotomy. There was no evidence of peritonitis. On following up the small intestine which presented, the last three inches of the ileum were found to be congested, and had a thick solid leathery feel. This was regarded as an intussusception which had been reduced in the process of manipulation. No other evidence of disease found. Boy made an uneventful recovery without pain. There was at no time any blood in motions.

In a recent thesis for the degree of M.D., Mr. Duncan C. L. Fitzwilliams has reviewed the records of a thousand cases of intussusception, and gives the following examples of spontaneous reduction as evidenced at operation.

CASE 17 (Mr. Fitzwilliams's case).—A male child, aged three years with a typical history of 30 hours' duration. No blood had been passed but a tumour was easily felt on the right side of the abdomen. At the operation no invagination was found, but the lower two inches of the ileum and the cæcum, with the adjoining mesentery, were congested [illegible]

[illegible] male infant, aged ten months, [illegible] and blood had been passed per an[illegible] the operation the tumour was found to be reduced, but numerous fresh hæmorrhages and petechiæ were seen on the bowel. One of the extravasations of blood was the size of a halfpenny.

Here again the evidence of a previous intussusception does not appear to be conclusive. Mr. Fitzwilliams adds a third case which had been under the care of Mr. T. H. Kellock and published by him.

CASE 19 (Mr. Kellock's case).[15]—Mr[illegible] with a history of two days' illness [illegible] pain, vomiting, and the passage [illegible] fæcal matter. Cessati[illegible] he was [illegible] anæsthesia. [illegible] stool containing a good deal of blood. Laparotomy. [illegible] he lower seven or eight inches of the ileum were quite collapsed [illegible] of a dull reddish brown colour, with one or two small hæmorrhages in the wall. Bowel above and below appeared healthy. Rapid and complete recovery.

In this case there may or may not have been an intussusception previous to the operation. Mr. Kellock refers to the influence of the anodyne in this case as aiding the reduction by quieting peristalsis. It certainly is a striking fact that in many of the cases described as spontaneous reduction the symptoms had persisted right up to the administration of the anæsthetic. One cannot help thinking that if reduction of the intussusception did occur, it was not exactly spontaneous but due to the influence of the anæsthetic in checking the excessive peristalsis or spasm and allowing the muscular action of the bowel to come into play in relieving itself.

Cases described as chronic or relapsing intussusception frequently show little conclusive evidence of that affection, and so far as the symptoms go may equally well be referred to a condition of effusion into the bowel wall. Without denying the existence of chronic or relapsing intussusception, of which I have seen undoubted examples, I think that some of the cases so diagnosed are capable of a different interpretation. The following two cases appear to me to have been due primarily to hæmorrhagic effusion into the bowel wall:—

CASE 20 (Dr. Still's case).[16]—Two days before admission a boy, aged two years, was seized with colicky pain in the abdomen, and passed a considerable amount of blood per anum on two occasions. Vomiting [illegible] the bowels had not acted. Eight [illegible] a similar attack, with the passage of [illegible] had been diagnosed at another hospital, where the patient was consi[illegible] Gradual recovery had followed. On [illegible] the adjoining parts of the transver[illegible] seemed to harden and soften. On rectal examination some [illegible] blood came away. The patient looked extremely ill, with sunken eyes, mucus on the corneæ, &c., and operation was not considered advisable. The provisional diagnosis wa[illegible] though Henoch's purpura was also considered. [illegible] place, with disappearance of the abdominal tum[illegible] came a recurrence of the symptoms, and a tumour was again palpable in the same situation. The child sank rapidly and died three days later. At the necropsy there were suppurative peritonitis and a large intussusception at the site of the tumour felt during life. The layers were only slightly adherent, so that the intussusception had probably only recurred quite recently. Dr. Still regarded the case as one of relapsing intussusception.

CASE 21 (Dr. Emil Dobell's case).[17]—A boy, aged eight years, was seized with acute abdominal pain and constipation. The colicky attacks continued, diarrhœa set in, and pure blood was passed per anum. Eight days after the onset purpuric spots on the legs, which later became general, and were accompanied by swelling and tenderness in many joints. From the age of three years the boy had suffered from similar attacks of colicky pain, which had been diagnosed as due to lead poisoning, and from joint pains, which had been regarded as rheumatic. On admission into hospital three weeks after the onset purpuric spots were present on the trunk and extremities, and the eyelids and feet were œdematous. The abdomen was retracted and a tender swelling was palpable in the sigmoid region. This tumour lay in the line of the colon, was firm and irregular, moveable, and apparently immediately under the abdominal wall. Relief from acute symptoms followed the use of oil enemata and much fæcal matter was removed. A week later came a recurrence of the purpura, œdematous swellings, and abdominal pain. The tumour was again felt, larger than before, while [illegible] to alter. The diagnosis of ileus from [illegible] to ileus from chronic or relapsing [illegible] flexure. As the attacks of pain and purpura continued, the patient was referred to a surgeon for operation. The surgeon could not discover any tumour either by abdominal or rectal examination. There was no recurrence of the abdominal pain, but hæmaturia set in and fresh purpuric spots appeared at intervals.

---

[13] British Journal of Diseases of Children, June, 1908.

[14] Common Disorders of Childhood, 1909, p. 121.

[illegible] 1904

[illegible] p. 123.

[17] [illegible] vol. xxxviii.

The final diagnosis was chronic intussusception from chronic constipation, with secondary purpura. The patient eventually made a complete recovery.

There does not appear to be any necessity to assume the existence of an intussusception in either of these cases. In Dr. Still's case there was an intussusception, the necropsy [illegible] ood from [illegible] months, [illegible] cases of [illegible] where the circulation in the invaginated portion is not seriously interfered with. Consequently, from the history of severe melæna in Dr. Still's case, it may be suggested that the primary trouble was intestinal effusion of blood, and that as the result of this intussusception occurred shortly before death, as has happened in other recorded cases.

This form of intestinal hæmorrhage may simulate certain affections of the colon such as mucous colitis, acute ileocolitis, and ulcerative colitis. In fatal cases there may be found extensive ulceration of the colon due to the sloughing of the mucous membrane at the hæmorrhagic areas, which are often diffused widely over the bowel.

[illegible] elsewhere.

This case may be variously interpreted, but from the attacks of pain I was led to believe that hæmorrhage had taken place into the bowel wall. I have seen similar symptoms in a young woman who was said to suffer from mucous colitis. In one of these attacks when she was under observation she passed large quantities of blood and mucus by the bowel and suffered from intermittent and colicky pain in the region of the colon. At other times she suffered from attacks of angio-neurotic œdema, the whole face becoming swollen and œdematous.

CASE 23 (Dr. Ashby's case).[15]—A boy, aged nine years, was suddenly seized with pain in the abdomen whilst at school, followed by the passage of blood and mucus by the bowel; the symptoms continued during the night. After admission next day he passed in the course of 24 hours 12 stools, consisting almost entirely of blood and mucus [illegible] invagination of the bowel if present. This was done but only an intensely congested colon was found. Death followed eight hours later. At the necropsy [illegible] severity.)

Ulcerative colitis is not a common affection in early life and some of the recorded cases seem rather to fall into the category of the affection we are considering. The post-mortem evidence is by no means conclusive, for it may not settle the question as to whether the ulceration was primary and the hæmorrhage secondary or *vice versâ*. In cases of Henoch's purpura I have seen definite ulceration of the colon which was clearly secondary to hæmorrhage into, and sloughing of, the mucous membrane. The presence of other hæmorrhages in the bowel wall is always suggestive of a primary h[illegible] A diagnosis [illegible] en the clinica[illegible] a condition of extensive hæmorrhagic effusion into the wall and the lumen of the bowel.

It is difficult to bring forward any evidence from the text-books of [illegible] crises fr[illegible] ignored and any examples are usually to be found classed under some other disorder. Without adding anything fresh I have tried to show by collecting a number of cases that the condition is one of considerable importance, and that there are various problems connected with it about which we require more information before any dogmatic statements can be made.

Wimpole street, W.

A CASE OF ACUTE MASTOIDITIS, WITH LATERAL SINUS SUPPURATION AND CEREBELLAR ABSCESS AS COMPLICATIONS OF THE OPERATION FOR THE REMOVAL OF TONSILS AND ADENOIDS.

BY L. A. PARRY, B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, BRIGHTON.

A CHILD, aged seven years, had an operation performed for the removal of tonsils and adenoids on Dec. 28th. She was kept in bed for five days, and was then looked upon as convalescent. Nine days later she was admitted to the hospital with the history that she had had ear trouble in both ears for four days. On admission the temperature was 100·6° F., pus was discharging freely from both ears, and on the right side there was a superficial mastoid abscess which was opened at once. The mastoid antrum was at the same time cleared out and found to be full of pus. No improvement resulted, and as the child was very ill, the temperature having risen to 104·2°, the wound was opened up 48 hours later. Pus was seen to be welling into the cleaned out mastoid antrum from behind, so the lateral sinus was exposed and the groove was found to be full of pus. The internal jugular vein was not considered at this time to be thrombosed. The child did not improve. She was desperately ill and had pyæmic symptoms. The temperature was 104·8°, and there was a little diarrhœa. On Jan. 15th, two days after the second operation, the internal jugular vein in the neck was divided between two ligatures; it was quite patent. The old wound was opened up and the sigmoid groove exposed more freely both in a downward and backward direction. The temperature remained high, up to 105°, for three days, and then gradually fell to normal. Convalescence was slow; it was a month before the child really showed much vitality. Early in February paralysis of the facial nerve of the side operated on became suddenly marked, but this disappeared without any special treatment, and the child was in March perfectly well. She was sent in very good condition to a convalescent home, and after being there about four weeks was readmitted to the hospital on April 29th because she had become drowsy, was sick, and had had a convulsion. On that day she was dull and apathetic, had a subnormal temperature, and a slow pulse. She was sick several times and had a few slight general convulsions soon after admission. As the symptoms of cerebral abscess were quite clear she was trephined at once over the cerebellum. This spot was selected in preference to the temporo-sphenoidal lobe as the lateral sinus groove had been diseased previously. At the first puncture of the cerebellum pus flowed freely by the side of the sinus forceps, a tube was put in, and in a few hours the child was sitting up in bed, quite lively. Drainage was difficult, the tube having to be readjusted and the track dilated on two or three occasions, owing to the reappearance of symptoms of cerebral pressure. Later a discharge of cerebro-spinal fluid was seen, [illegible] and the child died [illegible] the commencement of her illness.

Necropsy.—The right lobe of the cerebellum was converted into a large abscess cavity; there was a communication between it and the lateral ventricle of the same side, which, as well as the left ventricle, was full of pus. I think if it had not been for the last unfortunate complication (the communication of the abscess cavity with the ventricles) the child would have lived. I do not see how such a misfortune could have been avoided, nor what could have been done for it when it had occurred.

There are one or two points of interest in this case. First, acute mastoiditis and its complications is fortunately an exceedingly rare result of the operation for the removal of tonsils and adenoids. Neither of my two senior colleagues nor myself, in a very extensive experience of this operation, has ever seen it before. Otitis in its various forms is not uncommon, especially in those children who have had previous ear trouble (in this case no history of any ear trouble could be obtained). It is, I think, generally due to sepsis spreading up the Eustachian tubes from the raw surface left round the orifices by the scraping. I am sure I have seen this complication less frequently since I have adopted the plan of scraping only strictly in the middle line and leaving the few scraps around the orifices of the tubes alone. Another important factor in the avoidance of subsequent ear trouble is the after-treatment, a week in bed in a warm room being the most essential point. Secondly, it brings home closely to one the fact that this operation is not always the trifle it is sometimes thought to be. Many complications *may* follow it—e.g., ear trouble, suppuration in the lymph glands of the neck, hæmorrhage which may even be fatal, and so on. I think we should never tell the parents that the operation is a very minor one.

I am largely indebted to my colleagues, Mr. G. Morgan and Mr. H. H. Taylor, for advice and assistance in connexion with this case.

Brighton.

ORAL SEPSIS IN ITS CONNEXION WITH THROAT DISEASE.[1]

BY GEORGE IRVINE STEWART, M.A., B.Sc., M.B., C.M. ABERD., F.R C.S. ENG.,

COUNTY SCHOOL MEDICAL OFFICER, EAST SUFFOLK; LATE CHIEF ASSISTANT, THROAT DEPARTMENT, ST. THOMAS'S HOSPITAL.

1. *The Signs of Oral Sepsis.*

THERE are many more than are to be found in text-books. All of them can be categorised under the signs of inflammation of mucous membranes—redness, swelling, heat, pain, increased secretion, and loss of function. A peritonsillar abscess is the best example of an intense oral sepsis.

Redness.—This varies in intensity and can be general or local; locally it is most evident opposite a focus such as a septic tooth. In slight cases it is evident as a red line parallel to, but separated by one-sixteenth of an inch from, the border of the gums. As long as this red line is present there is oral sepsis. It is most persistent on the gums bordering the lower molars, and particularly the lower incisors. A characteristic reddening from oral sepsis is to be seen on the soft palate, as a red band half an inch broad commencing on the anterior pillar and arching round towards the centre of the soft palate, but just stopping short of the uvula. The remainder of the soft palate may be quite pale and the red band shows up very distinctly.

Swelling.—This is evident in most cases. It involves all the mucous membranes—of the gums; of the cheeks, which have the teeth plotted out in the œdematous swelling; of the tongue, which is similarly marked by the teeth; and of the lips. The swelling of the lips is most marked in infants, leading to a great protrusion and eversion of the lower lip.

Heat and *pain* are not extreme, but in some cases the breath appears hotter than normal, and discomfort causes the speech to be slovenly.

Increased secretion is evidenced in slight cases by the breaking of bubbles between the back part of the tongue and the soft palate when the mouth is opened. In the worst cases—e.g., in peritonsillar abscess—the dribbling is excessive. Dribbling is also well seen in the "teething" of infants, which is neither more nor less than a fairly intense stomatitis, and is most evident in bottle-fed babies in whom decomposition of milk is more likely to occur.

Loss of function.—Of all the signs of oral sepsis this is the most marked and has been the least recognised in its significance and its detrimental effects. It is characterised by diminution or loss of function of all the muscles of the oropharynx—viz., those of the pharynx, palate, tongue, cheeks, and lips. The buccal, oral, and lingual muscles are used for forwarding the food particles to the gullet, for keeping the mouth clear of food, for cleansing the mouth and teeth, and with the pharynx for articulation of speech. The teeth owe a great part of their cleanliness to proper tonicity of those muscles, and the moment their function is diminished by oral sepsis there is an increase of deposited muco-pus and an increase of oral sepsis; that is to say, a true vicious circle is started. The teeth that receive the least cleaning naturally can be readily identified—viz., the lower incisors and the lower molars, precisely the ones that show the red line, the sign of oral sepsis, longest.

The speech in oral sepsis, on account of the lack of tone in the muscles and from the discomfort caused by the swelling of the mucous membranes, becomes slovenly, partially guttural in character, the back part of the tongue being used in preference. It is so characteristic that perhaps the term "circumvallate" speech might be coined for this, as it is in the region of the circumvallate papillæ that the speech is articulated. An extreme case of this sort in a child where the speech was almost unintelligible was cured by proper use of the toothbrush (and the exercises in articulation by the teacher which before had been tried in vain).

The result of this loss of function of the muscles, to which I should wish to call most particular attention, is the dropping of the lower jaw and of the lower lip, which becomes thereby everted. The well-known open-mouth vacant expression usually attributed to adenoids and other nasal obstruction is really a characteristic of oral sepsis, which itself may be set up by nasal obstruction. The so-called "adenoid facies" is really that of oral sepsis, however induced. It is well seen in "teething" infants.

2. *The Effect of Oral Sepsis on the Throat Generally and Particularly on the Tonsils.*

My attention was first drawn to this by the need of finding other causes for laryngitis than "hysterical aphonia" and "nasal laryngitis." In throat hospitals the practice prevailed of at once depressing the tongue with the spatula, thereby concealing the teeth from view, without previously examining the state of the mouth. The practice of first drawing the cheeks aside to examine the state of the teeth is getting more and more universal. The following cases helped to emphasise the importance of oral sepsis in throat work.

CASE 1.—A male, aged 40 years, diagnosed by a well-known laryngologist as having tuberculous laryngitis. The cords were reddened and there was much muco-pus on the slightly swollen arytenoids. Quiescent tuberculosis was present at the right apex. He had a complete upper tooth plate lying on a row of septic stumps, each surrounded by florid granulations. Removal of the stumps on my advice cured the laryngitis in a month.

CASE 2.—A male, aged 19 years. His voice began to break four years ago. For the past two years he had been under treatment at a throat hospital for "squeaky" voice. The cords were reddened; approximation was incomplete. Removal of one stump and careful brushing of the teeth produced in six weeks such an alteration in the voice that his family and himself were continuously laughing about it. He had now a clear bass voice.

CASE 3.—The patient, a male medical practitioner, used to suffer from four or five severe colds every winter. He got severe septic stomatitis caused by sucking a post-mortem wound of the finger. Great attention has since been paid to cleansing the teeth. He now has one "cold" in two years on the average.

Seven elementary school teachers frequently off duty for loss of voice, quinsies, and sore-throat; since having the teeth attended to they have rarely any trouble.

Peritonsillar abscess.—Of 49 cases of this condition 47 had an extremely septic lower molar on the same side. One case (bilateral) had septic molars on both sides. The pus from those abscesses has the same characteristic odour as that from a dental antrum. The oral sepsis in those cases is extreme and is usually regarded as secondary; it is probably primary.

Unilateral enlargement of the tonsil.—Of 231 cases (in children of school age) of unilateral enlargement of the tonsil 135 had dental caries, mostly of lower molars, and oral sepsis on the side of the enlarged tonsil; 67 had dental caries and oral sepsis on both sides; 16 had no oral sepsis at all; and 15 had dental caries and oral sepis on the opposite side. I have never seen a case of unilateral inflammatory enlargement of the tonsil in an infant, in whom, of course, the oral sepsis is always bilateral. I believe that the organisms round septic teeth travel directly backwards along the sulci on either side of the lower jaw, and, meeting with the tonsil, settle there and cause its inflammatory enlargement. This [illegible] he red band of [illegible]

---

[1] A paper read before the Ipswich Clinical Society.

3. *Physio*[illegible] *Tissue in the Pharynx.*

In children the lymphadenoid tissue is more extensive than in the adult and is spread out on the wall of the pharynx, forming a complete ring continuous with the adenoid tissue in the naso-pharynx. The lower limit of adenoid tissue is very irregularly defined and may in cases reach the glottis. As age increases this adenoid tissue disappears and remains chiefly in the tonsil and the so-called lateral bands of the pharynx. It is possible that this disappearance is the result of the frequent attacks of catarrhal conditions in children, such as measles, scarlet fever, sore-throats and common colds, &c. Each attack would cause a degeneration of certain portions of adenoid tissue which would not be replaced. I would look upon the adenoid tissue in the pharynx as a protective barrier in which the attacking micro-organisms are dealt with actively, in which leucocytosis is most active and where immunisation of the body can be developed. Every attack of the invading micro-organisms would cause an inflammatory enlargement of the adenoid tissue, and in the fight certain portions of the adenoid tissue would be killed, so that the power of the adenoid tissue to resist invasion would be diminished by each attack. In addition, however, the numerous crypts existing in adenoid tissue act as good covering for the attacking organisms where they mass together for a further onslaught, which is rendered the more easy on account of the lessened resistance already produced, and once the adenoid tissue is severely degenerated it is not only useless as a protecting barrier but provides a point of vantage for further invasion.

The tonsil itself I would look upon as the special adenoid (lymphatic) gland of the mouth, lying openly in it, specialised it is true, but just in the same way that a Peyer's patch in the intestine is specialised. A tonsillitis would thus be an adenitis, and a peritonsillar abscess a periadenitis As a rule the tonsil and other [illegible] But occasionally the tonsil and adenoid tissue are overwhelmed in the attack, and the next link in the lymphatic chain becomes involved—viz., the glands at the angle of the jaw—and these take up the fight, undergoing enlargement in the process. If the attack is still more severe then the organisms no longer confine themselves to the mouth, but travel either upwards to the naso-pharynx or downwards to the stomach and lungs. Naturally when the tonsils and other adenoid tissue are already badly degenerated and act as harbourages for micro-organisms, the barrier power is extremely diminished and attacks of naso-pharyngitis and bronchitis become more and more frequent. I believe that the spread of inflammatory conditions from the oro-pharynx to the naso-pharynx by continuity is more frequent than is supposed. It must be remembered that Greville MacDonald long ago pronounced the nasal cavity to be normally free from organisms, while the mouth is normally crowded with them.

4. *Treatment and Indications for Such Based upon the Above.*

When inflammatory enlargement of the tonsils is recognised the treatment is that of enlarged glands in any part of the body: 1. Remove the cause. 2 If that is not sufficient, then the enlarged degenerated tonsil should be removed by surgical interference. Removal of the cause is the prevention or cure of oral sepsis, the extraction of septic molars, and careful mechanical cleansing of the teeth by brushing. This must precede surgical removal of the tonsil. In fact, the reckless way in which we all have removed tonsils without attending to the causal oral sepsis cannot be too strongly condemned. It is to my mind the explanation of why so many cases show unpleasant complications and bad results. Removal of the tonsils would be less indicated by their actual increase in size than by the evidence of their inefficiency, as shown by swelli[illegible] the jaw and by frequent atta[illegible] bronchitis. The use of the [illegible] during, and after tonsillotomy, and as a means of preventing attacks upon, and preserving the integrity of, the adenoid protecting ring cannot be too strongly advocated.

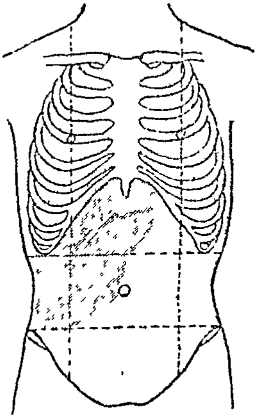
Ipswich.

A CASE OF PRIMARY SARCOMA OF THE DUODENUM.

By H. M. MACKENZIE, M B. EDIN., D.P.H. CANTAB ,
CAPTAIN, I M S , PROFESSOR OF PATHOLOGY, MEDICAL COLLEGE,
LAHORE, INDIA.

THE comparatively rare occurrence of primary sarcomatous growths originating in the small intestine, and more especially in the duodenum, lends some degree of interest to the present case.

The patient, a Hindu labourer, aged 18 years, was admitted to the Mayo Hospital, Lahore, on Dec 21st, 1908, under the care of Major H. G. Melville, I M.S , complaining of pain in the abdomen and back and swelling of the feet. [illegible] good and up to the date [illegible] always been fair. The [illegible] ays before admission, when he first felt pain in the abdomen and back, and some days later he noticed swelling of his feet. No treatment was adopted, but as the symptoms became more severe he came to hospital. On admission the patient, an anæmic, poorly developed youth, was suffering from pain in the abdomen, especially marked in the right hypochondriac and right lumbar regions and also from pain in the back in the middle line, the pain in both places being increased on pressure. He was markedly jaundiced and passed clay-coloured stools, but there was no diarrhœa or melæna. The urine was normal. The appetite was diminished and thirst was increased and the temperature was subnormal. On examination of the abdomen a large, moderately firm mass, moving with respiration and mobile on palpation, was found to occupy the right hypochondriac, right lumbar, and part of the epigastric and umbilical regions, as shown in the illustration, the inner margin being distinctly nodular.



The lower edge of the liver was palpable in parts, other parts being somewhat obscured, and light percussion gave a tympanitic note between the upper margin of the swelling and the edge of the liver, except on the right side where the dulness was continuous There was some [illegible] of the swelling towards the upper and inner margin. [illegible] malignant growth of the right [illegible] with dilatation of the gall-bladder from obstruction of the common bile duct. General symptomatic treatment was adopted, but the condition of the patient steadily grew worse and he died on Jan. 12th, 1909.

The post-mortem examination was conducted 24 hours after death. The body was that of an emaciated, poorly developed youth and showed very marked jaundice. Post-mortem lividity was slight and rigor mortis was present in the lower limbs only. The abdomen, which was retracted, showed slight fulness on the right side but no other abnormality externally. On opening the abdomen a large, fairly firm, but very friable tumour was found occupying the upper two-thirds of the right half of the abdominal cavity, extending downwards for about 5½ inches from the lower margin of the liver and from the right flank inwards nearly to the umbilicus. The duodenum disappeared into the centre of the mass, and several coils of small intestine were firmly adherent to its antero-internal surface, as was also the cæcum in the region of the appendix. The right kidney was considerably enlarged and partially imbedded in the growth from it could not be separated, but there was a sharp line of demarcation between the kidney substance and that of the tumour, and sections examined microscopically showed vestiges of the kidney capsule and no infiltration of the kidney. The right suprarenal body was enlarged to twice the normal size but was not adherent, while the ureter was patent and not affected. The pancreas was somewhat enlarged and adherent to the posterior surface of the growth. There was no connexion between the tumour and the liver, but the gall-bladder, which projected on to the anterior surface of the tumour, was dilated, containing over 4 ounces of thick bile, due to occlusion of the common bile-duct from pressure exerted by the tumour. The distended gall-bladder accounted for the fluctuation which was made out on physical examination. On following the duodenum into the tumour and laying it open, it was found to dilate into a cyst-like cavity some 3 inches in diameter, with rough, irregular walls, from the lower end of which it emerged again as a recognisable structure. Microscopical examination showed the tumour to have no capsule and to be composed of a stroma of fibrous tissue containing poorly developed blood-vessels and having the spaces filled with small cells. Some of these were irregular in outline, but the majority were of the round-cell type, with large deeply staining nucleus and faintly staining protoplasm. A delicate fibrillated intercellular substance could also be distinguished. The right kidney and the liver presented no specially noteworthy appearances, the kidney showing slight breaking down of tubular epithelium in places and the liver showing commencing monolobular cirrhosis with dilatation of bile capillaries. The pancreas, although adherent, showed no evidence of cellular infiltration. Successive sections of the duodenal wall from the point where it entered the tumour to the point of maximum dilatation of the cavity showed gradual disappearance of the structure of the glandular epithelium, followed by that of the muscular wall, until at the widest portion of the cavity there was no trace of intestinal wall, the wall of the cavity being composed wholly of tumour tissue of the nature described. Smears made from the contents of the cavity showed the ordinary intestinal bacterial flora and also many loose cells resembling those of the tumour in character. Some of the mesenteric glands showed enlargement, but microscopically no metastases were found, the enlargement being of the nature of a simple lymphatic hyperplasia. No secondary growths were found in any of the organs. Death appeared to be due to general cachexia and exhaustion, hastened probably by the toxæmic condition caused by the obstruction of the common bile duct. The rapid development of the primary tumour and the absence of any metastatic growths are noteworthy features in the case.

I am indebted to Major Melville for the report of the clinical symptoms and physical signs.

A CASE OF INHERITED TACHYCARDIA.

BY JAMES KIRKLAND, M.B., C.M. GLASG.

THE following case may be of interest to readers of THE LANCET. It clearly demonstrates that heredity plays a very active part in the etiology of tachycardia. I cannot find any other case reported having such a remarkable family history. Dr. A. W. Falconer in the *Practitioner* for February, 1909, records a case occurring in mother and daughter, and several other cases have from time to time been reported where the disease has been passed from a parent, usually the mother, to one or two children. But this case [illegible] the inheritance can be traced from [illegible] and descends to almost all the issue [illegible]

The particular member of the family now under my care, and whose case is here reported, is a male, 56 years of age, single, of no regular occupation, of independent means, of average build, but whose weight varies considerably (e.g., in February, 1906, he weighed only 6 stones 9½ pounds, in October, 1907, he weighed 12 stones 3½ pounds, and his present weight is 10½ stones) and who is 5 feet 10½ inches in height. He consulted me for nervous depression and tachycardia early in the present year. He has never been strong, having had pneumonia when six months old and peritonitis at 11 years of age. In 1897 he had a very bad attack of heart trouble—tachycardia, with hæmorrhage, supposed to have been from the lungs, but there was no trace of tubercle bacilli in the sputum, nor is there any now. This recurred in January, 1898. After several minor attacks he had a very serious one in October, 1900, followed by collapse. No record has been kept as to the rate of the heart beat, nor the length of time the attacks lasted. In 1901 he had nine attacks of a more or less serious nature, lasting from 18 to 21 hours. Bromide of potassium and morphine were used, evidently with success. In 1902 he had six bad attacks preceded and accompanied by "green sickness" and dyspepsia (flatulent). These lasted from five and a half to 23 hours. Bromides and morphine were pushed more strongly than in 1901. In February, 1903, there was a very bad attack and for the first time dyspnœa was recorded. In March, 1903, the patient had two attacks. On the first occasion irregularity was noticed, and this has remained a feature of the attacks ever since. On the latter occasion it is said that a gall-stone was passed. The "dark green sickness" was excessive and nothing seemed to give any relief until this stone passed. In April, 1903, "congestion of the base of the brain" was noted and strychnine was used for the first time. The attacks now became more frequent; all seem to have been accompanied by more or less dyspnœa, flatulent dyspepsia, and sleeplessness. There has also been a cough, with profuse frothy expectoration free from tubercle bacilli or blood. The irregularity at first would pass off with the attacks, but it is now (1909) constant. There was a rise of temperature on several occasions, but it was due, I think, to other causes. The patient could not eat anything but the lightest food on account of dyspepsia and consequent "heart hurry." One peculiarity that was noticed was the singular effect which hair-cutting or beard-trimming had upon the patient. It seemed to make him feel sick and faint, and he looked pale and haggard. So marked was this that his friends dreaded the ordeal and he himself postponed it as long as possible.

When the patient came to place himself under my care his heart beats varied from about 120 to 240 (the latter when an attack came on). There is a systolic mitral murmur and strong pulsation in the right side of the neck; on the left it is much less marked. The right lobe of the thyroid gland is enlarged and evidently acts as an irritant to the pneumogastric nerve; pressure upon this gland seems to excite the patient and to increase the frequency of the heart beat. The lungs are free from any defect in the apices, but there are moist râles in both bases. There is a varying amount of flatulent dyspepsia and a troublesome cough with profuse expectoration (free from tubercle bacilli). The urine is normal (specific gravity 1022) and the bowels are regular. The nervous system is far from satisfactory and the patient is melancholy and depressed. There is marked irregularity of heart action, which is greatly increased on any slight exertion.

Since I have had the patient under my care he has had only one attack of a serious nature. The heart beats were between 220 and 240. It was difficult to count owing to the irregularity. Dyspnœa was most distressing, increased by the cough and any slight exertion, even eating or drinking. The voice was much affected, amounting at times to aphonia. There were great abdominal discomfort and flatulent dyspepsia. The patient had to be propped up in bed, and was most comfortable and easy in this position and the dyspnœa was less severe. The attack came on suddenly after a walk that was beyond his strength, and lasted 28 hours, passing off as quickly. I tried many remedies without success, but finally a hypodermic injection of strychnine together with a mixture containing apomorphine hydrochlor. (1/16 grain), caffeine hydrobromide, &c., seemed to cut the attack short. I am now using 15 drops of digalen (a continental remedy and an extract of digitalis) thrice daily. It seems to have a very good effect upon the heart, which has greatly improved in every way since I began using it.

Family history.—This is most interesting, and I can find no case recorded with so marked a family idiosyncrasy towards tachycardia or so clear a history of heredity in this direction. The whole family practically seems to be subject to the disease. T[illegible] the family had marked [illegible] known whether it was act[illegible] was delicate as a young man, and he died from heart failure following influenza. One of the father's sisters suffered terribly from severe heart attacks, probably tachycardia, and she died from heart affection. The mother was threatened with pulmonary trouble in her youth, but this tendency passed off. She was all her life afflicted with intermittency of pulse, breathlessness, and palpitation. There were six daughters and three sons. The patient's two brothers are alive and both suffer at times from cardiac pain and palpitation, sometimes accompanied by slight dyspnœa. The eldest sister died at 28 years of age from pneumonia; she also suffered from cardiac discomfort with breathlessness. The second sister, who died at the age of 36 years, had splenic disease. She was married but had no children. She developed tachycardia from sea-sickness on a long voyage. The third sister died from peritonitis. In her case there was no apparent heart trouble so far as the patient knows. The fourth sister is still alive and is well but not robust. The fifth sister, who had pronounced heart trouble, died at 46 years of age from heart failure, and for the last three or four months of her life she was very ill suffering from tachycardia accompanied by dyspnœa. She was never able to take proper food, as tachycardia was sure to follow an average meal. The sixth sister died at about six years of age from concussion of the brain. She had dropsy which was said to be due to cardiac disease. The eldest niece has developed symptoms of tachycardia and cannot join in games, races, &c.

We thus see that both grandmothers, the father, the mother, the aunt, four out of six daughters, the three sons, and at least one niece were, or are, victims to heart lesions. The trouble did not show itself to any appreciable degree in most of these cases until at least early adult life. We cannot therefore say definitely how many of the fourth generation will escape, but from present appearances it is almost certain that more than the one will suffer.

Postscript.—Since I wrote the above notes of the case the patient died very suddenly during an acute attack.

Leigham Court road, S.W.

THE EFFECT OF DIPHTHERIA ANTITOXIN ON THE TUBERCULO-OPSONIC INDEX.

BY ALEX. G. BANKS, M.D. GLASG.,
LATE ASSISTANT MEDICAL OFFICER, METROPOLITAN ASYLUMS BOARD.

IN the *Liverpool Medico-Chirurgical Journal* for 1906, Vol. XXVI., Dr. T. R. Bradshaw and Dr. E. E. Glynn recorded in a series of nine cases the occurrence of low indices to the tubercle bacillus in patients previously injected with antidiphtheritic serum. The number of cases was not large enough to justify a very decided inference, and the following observations were undertaken with a view of clearing up the relationship. The subjoined tables give the results in a concise form.

TABLE I.

—	Before antitoxin.	24 to 48 hours after.	14 to 15 days after.
1	0·97	1·00	0·75
2	1·06	1·04	0·94
3	0·99	0·98	0·99
4	1·12	1·21	0·94
5	0·85	1·27	0·82
6	1·01	1·03	0·83
7	1·00	1·08	1·00
8	1·03	0·88	1·04
9	0·97	1·07	1·03
10	0·91	—	1·00
11	1·01	1·14	Died.
12	1·00	1·10	1·03
Average ...	0·99	1·07	0·94

It may be observed that all the cases examined were free from obvious signs of tubercle, none were under a year old, and the blood was submitted to examination within 24 hours of withdrawal.

TABLE II.

—	Index.	Amount of antitoxin.	Day after injection.	Age of patient.
1	0·91	60,000 units.	10th	—
2	0·93	12,000 ,,	22nd	4 years.
3	0·66	12,000 ,,	25th	4 ,,
4	0·78	21,000 ,,	26th	4 ,,

29	1·01	18,000 ,,	58th	2 ,,
30	0·97	30,000 ,,	72nd	7 ,,
Average ... 0·913		—	—	—

In no instance were less than 200 cells counted, the average number of bacilli being 2 to 3 per leucocyte.

From these results it will be seen that there is no great variation in the average index before and after the injection of serum. Nevertheless, a definite rise is apparent in the average index two days after injection, and this gains significance from the even distribution over individual readings. (Compare columns 1 and 2, Table I.) This was also noted in two of Dr. Bradshaw's cases. In Table II. the average index is within normal limits, but more than one-third of the indices are below 0·90, only six are above unity, while five are below 0·80. Arranging these according to the week in which taken, one half fall in the fourth and fifth weeks, giving an average of 0·86, and those during the sixth and seventh weeks 0·98 The other factors—age and dosage—seem to have little influence. As regards the former, the average index of those up to and including four years is about equal to the average of those between four and seven [illegible] total average. In the matter of dosage ag[illegible] from 15,000 to 60,000 units of antitoxin [illegible] same as that of those who got only from 6000 to 12,000.

One must conclude, then, that in healthy subjects the [illegible] is small, [illegible] re due to [illegible] 4 and 5, [illegible] figures. Table I. [illegible] Firstly, th[illegible] rise in the tuberculo-opsonic [illegible] of antitoxin; and secondly, that during some few weeks after this a somewhat low index to the tubercle bacillus is the rule. Also, these effects are independent of the quantity of antitoxin administered and probably of the age of the patient.

In conclusion, I have to acknowledge my indebtedness to

Dr. J. Brownlee and Dr. A. S. M. Macgregor of Belvidere Fever Hospital, Glasgow, whence I derived most of my material.

Glasgow.

A CASE OF MISSED LABOUR.

By PETER McEWAN, M.A., M.B., CH.B. EDIN., F.R.C.S. EDIN.,
RESIDENT SURGICAL OFFICER, ROYAL INFIRMARY, BRADFORD.

A MARRIED woman, 29 years of age, was admitted to Bradford Royal Infirmary on Oct. 24th, 1907, suffering from "abdominal tumour." Her menstruation had been regular until Oct. 19th, 1906, when her period ceased. In January, 1907, her abdomen became larger and continued to increase in size. Milk appeared in her breasts and she felt quickening. She had morning sickness and thought herself pregnant. The abdominal swelling gradually increased and the amenorrhœa persisted until May 19th, when she had a flooding followed by a slight reddish vaginal discharge, occasionally offensive, for ten weeks. She was in bed a few weeks; she had no febrile symptoms, and complained only of weakness. Since then she had two periods, one in September and the other early in October, both normal, but the loss was slight. She had no pain at these periods. She had had a feeling of weight in the pelvis, mainly on the right side, for the previous five months and her strength did not return satisfactorily. Her abdomen diminished in size from May 19th onwards. She had no trouble with the bowels or bladder except that she thought she had not been able to empty her bladder completely for some months, the act of micturition stopping suddenly. She had two children, six and seven years old respectively, and had had one miscarriage (at three months) four years ago, after which the patient was curetted.

On physical examination the patient was a dark brunette, fairly well nourished, with a slightly hectic flush about her cheeks. The mammæ were large and lax and showed a very well-marked areola and secondary areola; no milk could be expressed. The abdomen was distended to about the size of a seven months' pregnancy, and on palpation a rounded tumour could be felt rising out of the pelvis and extending about three fingers' breadth above the umbilicus. The upper limit of the swelling was rather higher on the right than on the left side, and its lateral margins were 1 inch from the right and 3½ inches from the left anterior superior iliac spines. The tumour as a whole had slight lateral mobility. It was firm in consistence, and in the right loin one could feel hard rounded bodies, and at times crepitus could be obtained. On vaginal examination the perineum was lax; the cervix parous, firm, slightly mobile; the os admitted the finger tip; the body of the uterus could not be felt apart from the rounded mass which filled the upper part of the pelvis and constituted the lower portion of the rounded abdominal tumour. There was a brownish discharge, slightly offensive.

On admission the patient's temperature was 103·6° F., the pulse was 130, and the respirations were 30 per minute. The tongue was coated. She felt quite comfortable. She remained in bed from Oct. 24th to 30th. She had a vaginal douche three times a day, large diet, and twice a gentle purge. She had an offensive vaginal discharge, reddish-brown, not much in amount, but coming away more freely after the douche. Her temperature remained high, with marked morning remissions, but even with a temperature of 103·4° she complained only of slight thirst and of feeling hot. The pulse varied from 98 to 126, and the temperature from 98° to 103·6°. Difficulty was experienced in attempting to pass the sound, and it was decided to examine the patient under an anæsthetic on Oct. 30th. Under ether the sound passed into the uterus for six or seven inches with ease, and it was decided to dilate the cervix and empty the uterus. The cervical canal was dilated first with Hegar's dilators, then with Bossi's dilators slowly and gently. The hand was then passed into the uterus and the shoulder of the fœtus was found presenting. The uterine wall was felt to be intact. The arm of the fœtus was pulled down; the head was cut off with a sharp hook; the body, then the head, extracted easily; the cord remained attached in utero. A good deal of dirty fluid escaped and the odour was exceptionally offensive. A coil of small intestine now appeared at the vaginal orifice, and when the hand was passed into the uterus was found to protrude from a rent in the posterior part of the lower uterine segment, slightly to the right of the middle line. The intestine was pushed up. The abdomen was opened by median incision. The omentum and bowel presented. A large flabby uterus, necrotic, adherent all round to various parts of intestine, was exposed. There was no sign of any attempt at contraction on the part of the uterus, and its wall was very thin, hardly thicker than stout brown paper, except in the region around which the placenta was attached. The necrotic wall had given way in several places besides that felt per vaginam. The upper part extended as far as the under surface of the liver, to which it was adherent. The "uterus" was dissected off from intestine and omentum; parts of the latter being necrotic were removed. A portion of the uterine wall was too closely adherent to be removed with safety and the surface was pared with scissors. The uterus and ovaries were removed and a few bleeding vessels were tied. Some necrotic tissue adherent to the under surface of the liver was scraped and a drain was left in the loin. Meantime the abdominal cavity was thoroughly washed out with saline solution. A packing of iodoform gauze was left as a vaginal drain and the abdominal incision was closed with through-and-through sutures of silkworm gut.

During the operation about two and a half pints of saline solution were injected intravenously and 20 minims of strychnine hypodermically. The patient's general condition was fairly good until near the end, when the pulse became small and weak, and she left the theatre almost pulseless. She had hot bottles, continuous rectal irrigation, and digitalin and strychnine hypodermically. Her pulse became countable, regular, about 170, and she regained consciousness in an hour or two, but she never rallied from the profound shock of the operation, and died in 15 hours.

The placenta was firmly adherent to and incorporated with the uterine wall. The umbilical cord was inserted about the centre. Only over the placental area did the upper part of the body of the uterus show anything approaching the normal thickness; in the other parts it was exceedingly thin, yellowish in colour, and tore readily when handled; there was no obvious muscular structure. The upper part did not bleed when torn. Near the cervix the muscular substance was apparent, but softer than normal and bled on cutting. The fœtus was a male, well developed, looking not much short of full time. The skin was white, and there were no blebs, areas of pigmentation, or shrivelling. The skull bones were well developed but separated, and exposed the membranes of the brain loose and shrunken. The genitals appeared to be nearly fully developed. The length from the heel to the natal fold was about five inches, of the upper limb about five inches, and from the heel to the lower part of the neck about 14½ inches.

Missed labour is so rare an occurrence that in this case the diagnosis was not made with certainty until the sound had been passed into the uterus under an anæsthetic; an attempt to pass the sound previously had been unsuccessful. No reason was found why the contents of the uterus should not have been discharged on May 19th, when there was apparently an attempt at premature labour. There was no tumour in the pelvis. The most interesting feature of the case was the necrotic condition of the uterus and its bearing on treatment. The uterine wall, except at the placental site, was exceedingly thin and friable, and incapable of any attempt at contraction or of being manipulated even gently without tearing. Consequently the treatment usually advocated, and that tried in the first instance—viz., the dilatation of the cervix uteri and the clearing away of the contents of the uterus per vaginam, was inadvisable. It appeared that it would have been impossible to deliver the fœtus per vaginam without rupture of the friable uterus. The fact that an emergency abdominal section had to be performed materially increased the length of time under anæsthesia and the shock of the operation. Had an abdominal section been performed first of all the patient would have had a much better chance.

In the *British Medical Journal* of Sept. 19th, 1908, a case of Missed Labour is recorded by Dr. A. Dempsey in which he dilated the cervix and emptied and washed out the uterus. The patient was seven months beyond the normal term of pregnancy. She made a good recovery. The interior of the uterus had a rough leathery feel. Dr. Oldham, on the other hand, records a case in which the contained mass is said to have worn nearly through the anterior wall of the uterus; and in Sir James Simpson's case, in which the patient died three months after term, the fœtus having undergone fatty metamorphosis, an opening of the size of half a crown had formed between the transverse colon and the uterine cavity, and the uterine walls were as thin as parchment. Hence although in some cases dilatation of the cervix and delivery of the fœtus per vaginam give the best chance of recovery, yet the danger of perforation of the uterus in other cases is so great that it is necessary, whatever the primary treatment adopted, to be prepared for opening the abdomen. The danger of perforation is no doubt greater when, as in the above case, the fœtus is not disintegrated than when fœtal bones are being discharged per vaginam.

The patient was under the care of Dr. T. Jason Wood, through whose courtesy I am permitted to publish the case.

Bradford.

HYDROA GESTATIONIS.

BY E. WARD, M.D. CANTAB., F.R.C.S. ENG.

So little is known of the pathology, the etiology, or the relationship of this remarkable disease that the following case is worthy of record.

A married woman, an octigravida, aged 26 years, came to see me in December, 1908; at that time she was five months pregnant. She complained of an eruption on both legs which she had noticed for about two days, and which was causing great suffering and loss of sleep from intolerable and continuous sensations of itching, burning, and tingling. She had had the eruption several times before, each time during pregnancy, and told me that it usually took ten weeks to cure; first a red and raised patch would appear, always in the same place, and on both legs; then "water" would form over it in blisters. These would join up to one large blister, and then burst, after which the whole area would become yellow and offensive, and the patient would be confined to the house for several weeks more until healing took place. There was no other complaint made, and the appetite always remained good throughout pregnancy in spite of the suffering and sleeplessness.

I found the patient to be a somewhat stout, but healthy, young woman of florid complexion. Her tongue was clean, her pulse was normal, and I could find nothing abnormal about her except the eruption on the legs. On each leg, [illegible] he tubercle of the [illegible] four inches, there [illegible] mb. The eruption was roughly symmetrical on the two sides, but whereas on the left side the leg was encircled, except for an area of normal skin one inch across, on the right side the band only extended round for something more than half the circumference. The reddened skin was hot and tense and raised considerably above the level of the surrounding skin. The surface was uniform and of uniform colour. The margin of the band was irregular but well defined and there were some outlying islands of eruption; the upper margin was more regular in outline than the lower. The affected area was not specially tender to touch, but manipulation increased the irritation. The leg was dressed with unguentum zinci benzoatis spread on lint, which was secured in position with a bandage and renewed daily. Small blisters appeared over the surface of the eruption, which later joined together, and in three or four days there was a [illegible] on both legs. This was [illegible] way and kept clean, and [illegible] normal again. When seen again on Feb. 26th, 1909, there were numerous marks of scratching over the affected area and some reddened and hard [illegible] the scratches. [illegible] return of the [illegible] where it had appeared still remained irritable. The pregnancy continued in a normal way.

The *previous history* of this patient, which was fully investigated to throw light on the eruption, was as follows. During a married life of six years and nine months she had had eight children and one miscarriage; there had been trouble with the legs during each pregnancy, including that which miscarried. The patient was married in March, 1902, when already seven months pregnant; the eruption had then been troubling her [illegible] just before Christmas, 1901. I [illegible] to a male child. In August, [illegible] h to twins, female children; from the sixth to the seventh month of pregnancy the eruption began to trouble her. In 1904, again while six to seven months pregnant, trouble began with the legs, and twin male children were born in August, 1904. A female child was born in August, 1905, and this time the legs were troublesome rather earlier in pregnancy. The miscarriage occurred in 1906, but the patient did not remember how far the pregnancy had proceeded, only that she had a rash on the legs as usual. In 1907 a male child was born, and on this occasion the woman thought she had escaped the eruption; it attacked her, however, the days following labour and ran the usual course. In 1908, when pregnant for the seventh time, the eruption first occurred at the fourth month and recovered in due course, only to reappear in the later months of pregnancy.

This history may be tabulated thus:—

Number of pregnancy.	Period of onset of hydroa.	Date of birth.	Sex of child.
1	4 months.	1902	Male.
2	6-7 months	1903	Female twins.
3	6-7 months.	1904	Male twins.
4	5 months	1905	Female.
5	4 months.	1906	Miscarriage.
6	Puerperium.	1907	Male.
7	Fourth month, relapse at the eighth month.	1908	Female.
8	Fifth month.	Still pregnant *	

* Since this article was written it has been ascertained that a relapse occurred in the ninth month of this pregnancy, but that the condition improved in 14 days. A healthy male child was born at full term.

The *family history* showed no case of a similar disease in any member of the family, and there were no other diseases in the family. The patient is one of 12, all brought up in rather hard circumstances and yet all living. Her father and mother are both aged 46, her five sisters are aged respectively 25, 20, 18, 16, and 13 years, and her six brothers aged 29, 23, 20, 17, 14, and 11 years.

This appears to be a clear example of the so-called erythemato-bullous type of hydroa gestationis, but there are nevertheless a few remarkable features.

1. The toxins of pregnancy had in this case quite an exceptional opportunity to produce their effects, as the pregnancies succeeded one another so rapidly, yet the eruption first occurred, early in the first pregnancy, as severe as [illegible]

[illegible] a band round [illegible] is of interest. [illegible] f "stocking" [illegible] is incidentally [illegible] anæsthesia met with in hysteria, [illegible] that we have much to learn about hysteria.

3. A statement of the patient that the eruption showed a tendency to [illegible] in December each year is partly borne out by [illegible] The reason why psoriasis and [illegible] appear especially at certain times of the year is not yet explained.

4. A study of this case leaves feelings of dissatisfaction with our present method of classifying these skin diseases. [illegible] the one hand to herpetic and bullous [illegible] on the other. A toxin which causes urticaria in one person may cause pemphigus in another, the eruption depending more on the skin of the patient, perhaps, than on the nature of the toxins. Some people blister more readily than others when burnt, and some people bleed more readily than others; the condition known as epidermolysis bullosa is only an exaggeration of the first type; these people blister with a pathological readiness. It will be with dermatitis herpetiformis just as it has been with osteo-arthritis. The joint changes described as osteo-arthritis are now known to occur from a variety of causes—from senile degenerative changes,

for instance; from chronic sepsis, as from the mouth, the nose, gastritis, constipation, or urethritis; and similar changes also occur in chronic rheumatism, in toxæmic arthritis, and in Still's disease; yet there remains another osteo-arthritis which is probably a specific infective disease. Hydroa gestationis is certainly one of the great group of diseases due to the toxins of pregnancy, but its exact relationship to other forms of dermatitis herpetiformis remains uncertain.

Llanelly.

DIFFICULTIES, DIRECT AND INDIRECT, IN THE DIAGNOSIS AND REMARKS ON THE TREATMENT OF CERTAIN FORMS OF DEAFNESS.

BY RICHARD LAKE, F.R.C.S. ENG.,
SURGEON TO THE ROYAL EAR HOSPITAL.

IN our dealings with unpromising cases of deafness other than those arising during, or as the results of, chronic suppuration of the middle ear we are, no doubt, considerably hampered by matters beyond our control. Amongst the foremost of these difficulties is the fact that we are often misled both in diagnosis and prognosis, either by an error in the interpretation of our testing or on account of the still very faulty and uncertain knowledge of the value of our tests, whether considered separately or in the aggregate. In our private practice we are often at a disadvantage, owing to having insufficient time to test completely and work out the case and to the unfortunate necessity of being expected to give an immediate prognosis, and these things, when coupled with the uncertainty of our methods of treatment, develop a further difficulty, which is that being placed in a position of trust by those who seek our advice it is a question as to how long we are justified in keeping them under observation.

In hospital practice there is, I suppose, no branch of medicine or surgery wherefrom any one class of patients derives greater benefit than that which is afforded, by operative or other treatment, to those suffering from suppurative conditions of the middle ear and their sequelæ; but, on the other hand, there is no class of hospital patients whose treatment is so inadequate as is that of those who suffer from perversion of hearing or deafness resulting from any other cause. For we are prepared to acknowledge that it not infrequently taxes us beyond our ability to give an accurate diagnosis and prognosis in similar cases in our private consulting-rooms, where at least 20 minutes, and often double that time, is devoted to investigation; and how, then, is it possible that in a hospital out-patient room, with its hurry and bustle, we can devote, one may say, even a tithe of the requisite time to each case that comes before us? For to be able to test a case properly it is necessary that much patient study and practice has been devoted to obtaining the requisite knowledge, and the greater the difficulties appearing in any given case, the greater is the necessity for quiet, and the more important it is in the interests of the patient that, comparatively speaking, time should be no object. It necessarily follows that a considerable part of this testing, if it is done at all, must be delegated to others, who may, without disparaging their assistance, be acknowledged to be wanting in that experience to which we have alluded. When to these difficulties is added the frequent inability on the part of hospital patients to grasp intelligently what is required of them, the strain and difficulty attendant on the work are greatly increased. Besides this, most of our important tests have to be considered as dealing with a dual individuality, as a comparison has frequently to be made between the tester and the tested, and very slight inaccuracies—whether they be due to inattention or what not—on the part of the examiner will give rise to errors. Nor does the importance of the personal element stop here, for there is no doubt that in testing low notes—that is, notes from the lower part of the scale towards the higher—these notes are capable to a certain extent of stimulating a sluggish auditory nerve, and so giving the slight fictitious impression of fair hearing when the upper notes are reached, and the striking of a fork in such a way as to produce over-tones may enable a patient who would be unable to hear the fundamental tone to hear the over-tone, and thus give rise to an error which may be of considerable importance from the point of view of prognosis. This matter of stimulating a sluggish nerve is perhaps most easily observed when using the Galton-Edelmann whistle, for if the tones are tested from above downwards, and a note is kept of the first tone which is heard, and then the process is reversed, it will be found that the patient is usually able to hear an appreciably higher note than that previously noted.

It often happens that some of our most interesting cases are those which for some reason or other have a claim on our services, and in this instance the financial side of the matter is eliminated, and therefore treatment may be continued for a longer period. It is from these cases, and not from our hospital practice, that we can acquire the most useful experience.

How are we to get over all this? We have practically no endowed chairs for the study of medicine in this country, and it therefore follows that all the aid we can hope for must come from the work we do and the results we obtain. My purpose, however, is not to give vent only to regrets, although it did seem necessary that I should explain, even at some length, a few of these contributory causes to our difficulties in the way that they appeal to me, and some of the reasons for our slow progress; although the most pessimistic amongst us must admit that we are no longer dependent upon the continental schools for our teaching of otology, and that much good work is being done in the British Islands.

This brings us exactly to the question of what we mean by unpromising cases of deafness, for these are the ones I allude to, and I think we may thus classify them: 1. Cases of slight unilateral paracusis or disturbance of hearing, in which no abnormality or departure from the normal can be detected in the tuning-fork tests, but only a diminution in the distance at which a whisper is perceptible. These cases are not improved by inflation, and they are in my opinion due to early nerve lesions, in which there is more or less loss of perception for fine and distant tones, which is only to be detected by whispering with residual air. 2. Cases of well-marked deafness with a double negative Rinné (Group ζ of my classification) with fixation of the malleus due to cicatricial changes within the middle ear, subsequent to previous inflammatory attacks, acute or subacute. These come under the heading of what is known as chronic dry catarrh of the middle ear in its most intractable form. 3. Cases of otosclerosis (Groups δ and ζ of my classification) usually associated with tinnitus or vertigo or both. 4. Deafness, &c., due to arterio-sclerosis.

Now as to the treatment of these various classes, it is unfortunately true that the first class seems to be very intractable, but this is one of the forms of deafness in which electricity offers some hopes of amelioration. With regard to the second group, it should not be included with those cases to which we have alluded here as unpromising unless the usual methods of treatment employed in such cases have failed to afford relief—that is to say, inflation of the middle-ear and the use of drugs, together with careful attention to nasal hygiene, including, if necessary, any operative measures indicated. There are certain tests which should be employed in these cases in order to obtain the most accurate information possible as to the condition of the ossicular chain. Thus by the use of Gellé's test we may be able to demonstrate that the stapes is freely mobile, although unfortunately we cannot ascertain with certainty by this method when the stapes is fixed. In these cases also it is very important that a careful investigation as to the mobility or otherwise of the malleus be undertaken. Thus in the second group, if the malleus is found to be immobile, whatever information we may derive from Gellé's test as to the condition of the stapes, one should proceed with that form of treatment which is most likely to restore its mobility, and it is in this class of case, if one is able to restore mobility to the malleus, that good results are to be obtained, for its mobility appears to have a distinct effect on the loss of hearing.

In the first place, otomassage should be employed and should this fail to give the necessary relief one may then, I think, proceed immediately to more drastic measures directed to the malleus itself, or one may try the effect of a hypodermic injection of fibrolysin or the internal administration of thiosinamin. The more drastic measures alluded to are attempts to directly mobilise the malleus by means of a steel probe cut to receive the short process and protected either by a small piece of cotton or guttapercha. Either a general anæsthetic is administered or the part anæsthetised by Neumann's method and the malleus forcibly mobilised. In doing this the external ligament is ruptured and the shortened tendon of the tensor tympani is able again to come into play. Inflation and otomassage should be regularly employed for some little time after the mobilisation has been accomplished. I have employed this method now for a considerable time and have obtained some most excellent results in cases which otherwise seemed doomed to life-long deafness.

In the third group, that of otosclerosis, there are certain cases, indefinite in number, but all too few, and yet a proportion which must not be neglected, in which, though from the very nature of the disease cure is impossible, a certain degree of relief may be afforded, and this improvement is often sufficiently marked to be a source of gratification to the patient. It is to be obtained by the use of the otomasseur, and the greater the number of revolutions per minute the greater the improvement. The exact rationale by which this improvement is obtained is certainly obscure, but it is most probable that it largely increases the blood-supply of the part, and has somewhat the same effect as that resulting from the employment of Bier's method of local congestion. In combination with this form of treatment I frequently inject a few minims of a fluid ointment containing 1 per cent. of red iodide of mercury. The ointment has great advantages over a solution, because one is able to use it stronger, it remains longer in contact with the part to which it is applied, and it does not lead to destruction of tissue. Occasionally quite brilliant results follow this treatment, and it also possesses the advantage that one is usually able in a very short time to demonstrate clearly either its utility or the reverse.

As regards the employment of otomassage, the best results seem to be derived from machines which will produce a high rate of velocity, up to 15,000 or 20,000 vibrations per minute. In fact it seems to me that we can consider the minimum pace as regards the number of vibrations per minute from which good results may be expected in cases of otosclerosis not to be less than 2000. It is no doubt difficult to lay down precise rules as to the time at which the otomasseur should be employed, but one may say this, that if there is any uncertainty as to the fitness of the case for its employment, half a minute should be the maximum time to commence with. One may say with decision that it is useless, if not positively harmful, in almost all cases where the Rinné test is positive and always where there is suppuration of the middle-ear, although I have seen patients so treated in whom one or other of these conditions was present. Where the Rinné test is positive, if this method of treatment be employed, the deafness will be increased and tinnitus may be induced unless, as given later, with a fixed malleus.

As there seems to be a considerable want of definite rules as to the employment of this valuable mode of treatment one may briefly enumerate the more important ones. Fixation of the malleus is at all times an indication for its use, though if there be a positive Rinné it must be very carefully employed and for more than 15 seconds at the commencement. Any tendency to giddiness, deafness, or tinnitus should be immediately noted and if necessary the treatment entirely suspended. This is the only instance in which a positive Rinné admits of the employment of the otomasseur. All cases of otosclerosis demand its employment. The main point to bear in mind is that if it is possible to act upon a mobile stapes otomassage will do harm and not good, except in those cases where the malleus is so fixed that no movement is imparted to the stapes, although it were otherwise capable of mobility. The rôle played by fixation of the malleus in cases of intractable forms of deafness of only moderate severity is very large as we have stated, and if its mobility can be restored quite excellent results follow in a large number of cases. As has been stated earlier in this paper, it is important that these cases should be seen from time to time in order to prevent re-fixation or recurrent ankylosis.

W[illegible] ver[illegible] me[illegible] may be afforded. This, however, is not obtained by means of aural therapeutics, but the cases should be transferred for treatment to the physician. If, as seems possible, otosclerosis has a definite connexion with rheumatoid arthritis, the newer forms of treatment which are suitable for that disease may possibly aid us in the earlier stages of this condition.

In conclusion, it is well to state emphatically that in all but the second group of cases under consideration no operative procedure whatever appears justifiable. In fact, it seems to me that to recommend such procedures shows an ignorance so grave that it is difficult to put the matter sufficiently strongly.

Harley street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF HAIR-BALL IN THE STOMACH.

BY G. P. NEWBOLT, F.R.C.S. ENG.,

AND

R. A. JONES, L.M.S.S.A. LOND.

ALTHOUGH a number of cases of hair-ball in the stomach have been recorded by different observers they can hardly be described as common. At the same time it is well to bear in mind the fact that they do occur when dealing with abdominal tumours situated in the epigastrium in young females. Knowsley Thornton, in THE LANCET of Jan. 9th, 1886, describes a successful case, the second on record. In 1895 Paul Swain describes a third, and they occur at intervals in the literature after this date, but the majority of those described have been found post mortem. Although common in animals, in which the hair tends to "felt," the mass becomes ball-shaped, whilst in the human subject the hair takes the shape of the stomach and r[illegible] condition. In many of the [illegible] insanity, but not in all. On[illegible] intelligent, and in my own [illegible]ances quite sane. If not removed the tendency is for the mass to cause ulceration and perforation or vomiting and death from exhaustion. In a case described by Dr. H. Mallins the ulceration had exposed the pancreas and also the transverse colon. The diagnosis has to be made from splenic tumour, retro-peritoneal sarcoma, pancreatic cysts, and tuberculous glands, but the most important information to get is the early history with regard to eating hair, string, &c. In Swain's case the mass weighed 5 pounds 3 ounces, the largest on record, and the stomach incision was six inches long, the mass was broken up before removal, and the stench was very offensive.

In August, 1908, whilst on a holiday in North Wales, I (G. P. N.) saw a young woman, a dressmaker by occupation, in consultation with Mr. R. A. Jones of Menai Bridge. She was 22 years old and had b[illegible] plaining of pain in the epig[illegible] flatulence and constipation. [illegible] by lying down. She had to lie in bed from October until December, 1907, on account of these symptoms, and during this period she lost flesh. There was a history of her having swallowed a piece of string half a yard long before the commencement of this illness. When doing her hair she was in the habit of putting the ends of some of the plaits into her mouth. She had also swallowed some bits of cotton. The girl was not hysterical, but was very anæmic. In December, 1907, she passed a ball containing hair and a piece of string with some bits of cotton, but as her symptoms continued she went into a hospital in May, 1908, for treatment, but only remained there for some ten days, after which she returned home. On examination I found her to be a very anæmic girl, complaining of dyspeptic symptoms and unable to take much food on account of pain. In the left hypochondriac region extending across the median line to the right was a large moveable abdominal tumour. It was smooth and flat on palpation, painless to the touch, and moveable from side to side. Apparently it was in connexion with the stomach but its exact nature was not diagnosed. An x ray photograph taken after the administration of bismuth showed a beautiful picture of a tumour occupying the whole of the stomach area and extending into the duodenum.

On Sept. 29th, the patient being under ether, the mass could be moved freely about the abdomen, but lay on the left side opposite the umbilicus when not disturbed. It felt quite solid and hard. A free incision was made in the left linea alba and the abdomen opened in this situation; the stomach at once came into view, and on examination it was evident that the tumour consisted of a mass contained in the stomach itself. The organ was brought outside the abdomen and packed around with gauze; a transverse incision was made from the lesser curvature across the stomach to the greater curvature and a mass of hair was exposed. After its removal the incision was closed with two layers of suture, one taking all the coats of the stomach and the second (a Lembert) taking the peritoneum. Some adhesions at the cardiac end were dealt with and the abdomen was closed. The operation was unattended by complications and the patient returned home on Oct. 23rd. Two or three days later she had a severe attack of gastritis and was very ill for some days. I saw her on Nov. 5th when she was better, and later I heard that she was quite well again. The mass removed was composed of black hair and weighed 9 ounces. It was rather offensive to the smell and the portion which was in the duodenum was bile-stained. It was 7 inches long, 3½ inches broad, and 2 inches in thickness.

Osler, fourth edition, says there are 16 cases in the literature and the following are some of those on record (no doubt there are many others):—

Knowsley Thornton, THE LANCET, Jan. 9th, 1886, p. 57; recovery. Schonborn of Königsberg, Langenbeck's Archiv, 1883, vol. xxix.; recovery. Bandemant, Journal de Médecine, vol. ii., p. 507, 1779. Pollock, Transactions of the Pathological Society, 1851–52, p. 327. George May, Medical Association Journal, vol. ix. Russell, Medical Times, 1869. Inman, Medical Times. Best, Brit. Med. Jour., 1869. Sir W. Gull, Transactions of the Clinical Society, vol. iv. Paul Swain, THE LANCET, June 22nd, 1895, p. 1581; recovery. Berg of Stockholm, Nordiskt Medicinskt Arkiv, recovery. E Percy Paton, Transactions of the Clinical Society, January, 1902, recovery. H. Mallins, THE LANCET, June 6th, 1903, p. 1592. S. S. Rather, Human Hair in the Stomach, Texas Medical Journal, Austin, 1905–06, vol. xxi. p. 358. G. F. Still, THE LANCET, May 16th, 1908, p. 1412; recovery.

A CASE OF WOUND DIPHTHERIA.

By **RANDAL HERLEY**, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,

HOUSE SURGEON, GENERAL INFIRMARY, DEWSBURY.

ON May 21st, 1907, a youth, aged 18 years, struck the corner of a shovel with the back of the left hand whilst "taking a jump" in a field. One of his companions used the shovel for marking the jumps. The wound was a "small hole"; it did not bleed much, and the boy dressed it with adhesive plaster. On June 16th he complained of pain in the left axilla, the left hand was swollen, and, acting on the suggestion of a neighbour, a bread-and-milk poultice was applied by the lad's mother. On the 17th he came to the infirmary, and on examination I found a sore on the back of the left hand which in many ways resembled a well-developed anthrax pustule; the hand was swollen and the axillary glands were enlarged and tender. The temperature and pulse were normal; there were no soreness of the throat and very little constitutional disturbance. I sent a swab to the Public Health Laboratory, Wakefield, and received the following report on June 19th:—"No anthrax bacilli could be found in this specimen, either on immediate examination or as the result of inoculating culture media. Typical diphtheria bacilli, however, were present in large numbers." A swab from the throat was examined with a negative result. As to treatment, the wound was scraped, pure carbolic acid was applied, and 4000 units of antitoxin were injected under the skin of the abdomen. The dressing was a boric acid fomentation. The boy was quite well in three weeks. I was unable to trace the source of the infection.

In Osler's "Principles and Practice of Medicine," I find the following:—"Wound diphtheria may occur without demonstrable connexion with cases of diphtheria and without affection of the throat in the individual attacked, but such occurrences are rare."

Dewsbury.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Gastro-intestinal Crises from Effusion into the Bowel Wall.

A MEETING of this section was held on June 22nd, Dr. S. J. GEE being in the chair.

Dr. G. A. SUTHERLAND read a paper on Gastro-intestinal Crises from Effusion into the Bowel Wall. This is printed in full in this issue of THE LANCET (see p. 1817).

In the discussion that ensued, Mr. ARTHUR EDMUNDS showed coloured pictures and drawings illustrating the case of a boy, three years of age, who was suddenly seized with acute abdominal pain and vomiting. On admission to hospital an indefinite swelling was felt and intussusception was diagnosed. When laparotomy was performed the appendix was found to be hæmorrhagic and was removed; an intussusception was not present. The wall of the appendix was swollen and infiltrated with blood. Mr. Edmunds showed that in cases of spontaneous recovery from intussusception, the site of the intussusception was marked by a pallid œdematous area.

Mr. HUGH LETT observed that in cases of intussusception, which occurred mostly in infants, what guided him in determining on operation was the presence or not of a tumour. In his experience a tumour could be felt in most cases of intussusception.

Dr. SUTHERLAND, in the course of his reply, pointed out that the presence of the pallid œdematous area described by Mr. Edmunds furnished a means of differentiating between a spontaneously reduced intussusception and a case of hæmorrhage into the bowel wall. In regard to the frequency of a tumour being felt in cases of intussusception, Dr. Sutherland thought that Mr. Lett put the incidence of their being observed higher than was generally taught, but the difference was probably due to the methods of examination followed.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.—Congenital Obliteration of the Bile-Ducts.—Congenital Dislocation of the Hip-joint.

A MEETING of this section was held on May 28th, Mr. R. CLEMENT LUCAS being in the chair.

The following resolution, sent up by the Council, was passed by the meeting:—

> That in the opinion of this meeting it is desirable that the Board of Education should issue forthwith a complete set of forms for use in the medical inspection of elementary school children, in accordance with circular No 582 issued by the Board on Jan. 23rd, 1908, and should issue definite instructions to medical officers as to the manner in which the medical inspection shall be carried out.

Dr. F. LANGMEAD showed a case of Facial Irritability of 15 months' duration succeeding tetany in association with dilatation of the large intestine. The girl, aged eight years, was admitted to hospital for tetany in April, 1908. Her facial irritability was pronounced on both sides. No signs of organic nervous disease were found. The colon was dilated. Attacks of laryngismus stridulus occurred. The urine contained indican. The colon was daily washed out, whilst castor oil and salol were given by the mouth. Saucrin, koumiss, and thyroid were also used without effect. The washing out was discontinued and energetic treatment with bismuth and opium applied. Enemata and massage were then used for a week with improvement, and after two months she had gained four pounds in weight and the tetany and laryngismus had subsided. The massage was continued for three months. The signs of dilatation of the colon then disappeared, but the facial irritability had persisted. A month or two ago she had another attack of tetany with vomiting. Dr. Langmead referred to nine cases exhibiting relapsing tetany, dilated large intestine, and unhealthy offensive motions occurring at an age beyond that of the usual infantile tetany. All had died except the patient exhibited. On tapping the cheek of the child an immediate rapid contraction of the muscles on the same side of the face was elicited.—Dr. ROBERT HUTCHISON asked [illegible] the condition was congenital or not.

Dr. G. CARPENTER showed: 1. A specimen of Hypertrophic Stenosis of the Pylorus removed from a three weeks old female child. 2. A specimen of Morbus Cordis with Complete Transposition, including the liver, spleen, and large intestine; there was also a cyst in the tongue and a solitary kidney. The condition was not diagnosed during life, and no symptoms were observed pointing to heart disease. The child became worse and had fits two days before death.

Mr. CLINTON T. DENT gave [illegible] tion of the Movements of the S[illegible] Abdominal Wall in a case [illegible] Stenosis of the Pylorus. The [illegible] and weighed 8 pounds on birth and 5 pounds on admission to hospital, 11 days before death. It was not considered safe to operate. The pylorus could be felt dis[illegible] that the post-mortem examination showed the whole pyloric canal to be in a state of hypertrophy. The mucous folds were well marked, and he had no doubt were, as is usually the case, the final cause of the obstruction.—Mr. LUCAS expressed the indebtedness of the section to Mr. Dent for his excellent demonstration.

Dr. ERIC PRITCHARD showed a case of Unilateral Hypertrophy of the Hand from Macrocheiria in a boy aged 10 years. The left hand was observed to be larger than the right shortly after birth. A capillary nævus was also noticed to extend in an irregular manner up the arm and down the left axilla. [illegible] to [illegible] tha[illegible] other member of the family. The left hand was larger than the right in the ratio of 9 to 5 as determined by displacement of water. [illegible] though it [illegible] The [illegible] mina[illegible] o be a [illegible] Dr. [illegible] eased blood supply dependent [illegible] vessels, or the arterial vessels, or the lymphatic vessels, or any combination of the three.

Dr. PRITCHARD also showed Symmetrical Helical Fistulæ with Branchial Fistula in an Infant. The case resembled one shown by Mr. J. Howell Evans at the June meeting, 1904. It showed two symmetrical fistulæ at the anterior aspect of the helix of the ear about two millimetres in diameter and the same in depth. At times they both emitted a thin secretion. On the left side of the neck, at about the level of the anterior margin of the sterno-mastoid muscle, was a small depression representing in the usual position the vestigial remains of what was once a branchial cleft. In front of the right ear there was a small nodule or preauricular tubercle. No other stigmata were shown. Similar helical fistulæ had occurred in several members of the family. The mother, who was present, showed them on both ears, and so did four of her children, deceased. The maternal grandmother and two of her sisters also had symmetrical [illegible] fistulæ.

Mr. J. A. BOOTH and Mr. J. HOWELL EVANS showed [illegible] of Conjoined Twins. Mr. Howell Evans said that Mr. [illegible] had attended the mother of the twins, but they were born before his arrival. The method of presentation seemed to have been normal, the cephalic position for the first child, the legs of the second [illegible] down, and the birth was [illegible] the type of twins which [illegible]—namely, those joined by [illegible] The radiograph [illegible] were joined with more than fibrous [illegible] c genitalia were complete, there [illegible] e rectum of the second child opening into the rectal ampulla of the first. The mother was one of twins and there had been other twins in her family. Several members of the father's family had had congenital heart disease. The twins were now about a year old. C[illegible] lived to considerable age [illegible] bronchitis which bega[illegible] administered to both, but in spite of this the second child also had bronchitis. Separation had not been attempted on the ground that the twin which seemed to be weaker appeared to have the greatest amount of alimentary canal.

Dr. G. A. SUTHERLAND showed for the second time a case of Cirrhosis of the Liver in a boy, aged 11 years. Ascites had recurred and 150 ounces of clear fluid had been drained off, since when tapping had been repeated at intervals. He had had seven doses of fibrolysin without any effect at present. Dr. Sutherland asked whether the surgeons could [illegible] the case was one of chronic recur[illegible] s asked what Dr. Sutherland [illegible] the condition and what was the [illegible] r. SUTHERLAND replied that there was no evidence of adherent pericardium. He did not know that syphilis had been excluded, but mercurial treatment as a method of cure had been tried in vain. Still, in advanced cases of syphilitic liver this would be the case. The mother died two years ago from alcoholism, but there was no evidence of the patient having been given alcohol.

Mr. SYDNEY STEPHENSON showed a case of Oxycephaly in a boy, aged 32 days, who was admitted to hospital with ulceration of the right cornea. The right eyeball protruded from between the eyelids immediately after birth. The labour was easy. The eye bulged forth whenever the baby screamed or was bathed. The child weighed 5 pounds, had a red and wrinkled skin, loud "snuffles," and a slight papular rash on the hands and arms and trunk. The skull was typical of oxycephaly, the frontal region rising steeply and overhanging the face. The cranium was deficient as regards total size and capacity. [illegible] present. [illegible] ent though [illegible] orbits were clearly deficient in depth.—Mr. LUCAS said that those interested in such [illegible] that at the Royal College [illegible] skulls had been arranged i[illegible] Dr. A. Keith.

Dr. H. MACCORMAC showed a case of Congenital Laryngeal [illegible] a Congenital Oblitera[illegible] rrhosis. The patient, a boy, aged three months, was admitted to hospital suffering from malnutrition and jaundice of moderate degree. The mother said the child had been jaundiced from birth. No other member of the family had jaundice. The mother had had no miscarriages. The child's liver was enlarged but not tender. The fæces were acholic and rather copious. The [illegible] two granular casts. [illegible] cells, 3,900,000; [illegible] by Dr. J. C. G. Ledingham): Polymorphonuclears, 61 per cent.; large lymphocytes, 26 per cent.; eosinophiles, 3 per cent.; small lymphocytes, 1 per cent. In a month the child had gained one pound and the jaundice began to diminish. The spleen, however, had increased in size, for its lower border could be felt one inch below the costal margin. The improvement then ceased, and after two months in hospital the temperature was frequently raised to 101° or 102°. At the age of five months convulsions set in and the child died. At the necropsy the gall-bladder was represented by a fibrous [illegible] bile-duct was hardly pervious. These [illegible] ere doubtless partly inflammatory in [illegible] were unaccompanied by congenital [illegible] the body. The hepatic cirrhosis was found to be chiefly of interacinous distribution, and was doubtless to some extent a result of the obstruction.—Dr. H. D. ROLLESTON said that Dr. Weber's case differed from the ordinary run of cases of congenital obliteration of the bile-ducts. The distribution of the fibrous tissue was different, and there was a curious condition about the [illegible] enlarged [illegible] together [illegible] in the portal fissure by an inflammatory condi[illegible] ducts. The question arose as to whether it might be a case in which the obstruction of the ducts was produced outside the ducts. The only point against that was the practical obliteration of the gall-bladder. His own belief was that there was no congenital narrowing of the ducts at first, but that from the beginning it was an inflammatory toxic process. This was contrary to the view now held by Dr. Thompson and advocated in America.

Mr. A. RALPH THOMPSON read a paper upon Congenital Dislocation of the Hip-joint, and showed a number of specimens clearly illustrating the points which arose. He put forward the view that the changes associated with pressure or static dislocation of the hip are too frequently regarded as primary and as producing the dislocation, whereas in many cases of congenital dislocation no deformity is noticed until the child begins to walk, and the deformity occurs in well-developed female children in whom the mechanical conditions are more likely to produce dislocation at the time of the adoption of an erect attitude than is the case in males. The changes found are a shallow and triangular acetabulum, a small flattened head of the femur with a short and anteverted neck, deficiency in the iliac segment of the acetabulum and hour-glass constriction of the capsule, a stretched or absent ligamentum teres, and some coxa valga and shortening of the leg below the knee. These conditions could all be explained by considering the mechanics of the joint in children of two to three years. Mr. Thompson gave full demonstrations of these points.—Mr. HUGH LETT said the section was very much indebted to Mr. Thompson for his paper, which had evidently been produced with a great amount of care, and much work had been entailed. The theory he brought forward was very interesting and important. All who had seen cases of congenital dislocation of the hip must have been struck with the remarkable fact that many cases did not appear to have anything wrong until they were three or four years of age. He would like to consider the paper more carefully before speaking very decidedly about it, but there was much, from an anatomical point of view, in what was brought out, particularly in connexion with the fœtal pelvis and the relations of various lines of force in male and female. He believed Mr. Thompson's view would be accepted by very many authorities, and those who did not accept it would be bound to weigh it with great care before putting it on one side.—Mr. LUCAS said that he had been accustomed to point out that when a child had been taken off its walking on one limb from any cause not only the thigh but the foot and all the bones of the limb were shortened as a result of the lack of use. He understood from the argument that as the female was less protected than the male from dislocation of the hip, it was unwise to place the female child on her feet so early as the male child.

EDINBURGH OBSTETRICAL SOCIETY.

Manipulation and Axis Traction.—Peritonitis and Fibroids.

A MEETING of this society was held on June 9th, Professor W. STEPHENSON (Aberdeen), the President, being in the chair.

The PRESIDENT read a paper on the Value of Manipulative Action in combination with Axis Traction in Forceps Cases. He said: In recent times the principle of axis traction has so monopolised the obstetric mind that in some quarters direct traction in the line of the pelvic axis is the sole engrossing idea in instrumental delivery. The object should be to deliver skilfully and with a minimum of force, and this requires other methods to be employed besides simple traction in one line. The main error lay in discarding the use of the ordinary handles and extracting solely by the traction rods. There are two factors, the pelvic walls and the fœtal head. In the system of axis traction as now practised, the attention is concentrated too much on the curve of the canal, the lie of the head is left out of account. Forceps are often required in a normal pelvis due to the unfavourable relations of the head, yet in the latest approved forms of forceps the parts whereby change in position can be facilitated have been rendered worthless for the purpose. Those who discard the handles throw the burthen of effecting the movements of adaptation wholly on pressure between the head and the maternal tissues. In simple cases with normal conditions traction in the pelvic axis is sufficient, but where abnormal conditions are present the necessary movements can be effected with less force and less risk of injury by a gentle manipulative action through the handles than by a strenuous pull in one line. This manipulative action is to favour and to effect, by means of the handles, such movements of the head as experience has taught are necessary in delivery, as flexion, rotation, or a combinatio of the two. Manipulation does not mean the pendulum action nor twisting an occipito-posterior position into a anterior. Many generally accepted views misrepresent th mechanism of labour. So-called flexion of the head is no rotation on an *internal* axis, but partakes of the nature of *rolling* of the head on the frontal bone as a pivot by a arrest for the time being of the forehead while the occipu is free to move. The occiput does not rotate in the pelvi into the conjugate diameter and the face into the hollow o the sacrum. In its exit from the bony canal the head lies i the oblique diameter of the outlet, the posterior parietal bon on a lower level than the anterior. From this position th head passes over the perineum, not by extension as usuall described, but by a combination of two rotations, the on being the familiar wheeling of the head round the pubes, the other a rotation whereby the long diameter of the head passes from the oblique nearly into the conjugate and th two parietal tuberosities come to be on the same level. To discard the use of the handles is to throw away much valuable information which is transmitted through them to the hand, regarding the command of the blades over the head, whether the hold is good or the forceps are slipping; the hand is quicker than the eye to detect the forward movement that guides the direction of traction. When held properly the grasp should in no way interfere with, but on the contrary aid, the natural rotations; recession of the head can also be aided and too forcible or precipitous expulsion resisted. Thus the hand works intelligently with nature. The special conditions which can be helped by manipulation with forceps were discussed and demonstrated on models, such as that of favouring the rolling movement of the head at the brim and adaptation of the head to the widest diameter of the brim in flat pelvis. He combined the axis traction to the previous form of forceps by applying a hook on the blades above the handles and pulling backwards with it. He considered the older form of forceps much preferable to the axis-traction form.—Dr. A. H. F. BARBOUR was much interested in the details of the manipulations that could be effected by the forceps of Sir James Y. Simpson. The Milne-Murray forceps differed from them in that one could not control the handles in the same way. With the axis-traction forceps the operator literally worked in the dark, leaving the head to find its way through the pelvis by pulling in the line of least resistance. For the ordinary practitioner he believed this latter was the best, but it was very interesting to find that the old forceps could effect the same with skilled manipulation.—Dr. R. G. MCKERRON (Aberdeen) referred to the fact that the President had shown that traction in the axis was not always the best and often required too much energy, and that there were cases where the axis of traction, as indicated by the rods, was not true. Too much attention had been bestowed on the pelvis to the neglect of the position of the head.—Dr. F. W. N. HAULTAIN said that there was no comparison between the old forceps and the axis traction, but the President had stated a good case for manipulation as well as pulling. Labour was the accommodation of an irregularly shaped body passing through an irregularly shaped canal, and during this process two powers were at work, one pressing from above, the other resilience from below. The process stuck at times; then an extra force was needed, or moulding, or manipulation, or adaptation. All would agree that manipulation could do a great deal with traction.—Dr. JAMES RITCHIE and Dr. J. HAIG FERGUSON also discussed the paper, and the PRESIDENT replied.

Dr. JOHN MCGIBBON read a paper on Peritonitis as a Complication of Fibroids, specially in association with Torsion of the Pedicle, with an illustrative case. The patient, aged 31 years, was seized suddenly with violent abdominal pain and vomiting. In 12 hours she showed all the symptoms of peritonitis. The symptoms subsided in ten days. Operation was then performed and revealed a fibroid with twisted pedicle. Noble and Steinbüchel had described similar cases. Gillmore had recorded a case which had been mistaken for appendicitis. Dr. McGibbon decided against immediate operation at the onset of the symptoms partly on account of the amount of shock present.—Dr. HAULTAIN considered immediate operation always the best.—Dr. BARBOUR did not believe anything could be gained by delay in operating.—The PRESIDENT also discussed the paper.—Dr. MCGIBBON replied.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A general meeting of this society was held on June 11th.—The following officers, amongst others, were duly elected by ballot:—President: Dr. Leonard Williams, London. Vice-Presidents: Dr. Charles Begg, Bath; Dr. Samuel D. Clippingdale, London; Dr. T. F. Gardner, Bournemouth; Dr. W. R. Huggard, Davos Platz; Dr. W. Black Jones, Llangammarch Wells; Dr. Percy G. Lewis, Folkestone; Mr. A. L. Mackenzie, Bath; Dr. F. A. de T. Mouillot, Harrogate; Dr. F. M. Sandwith, London; Dr. Ernest Solly, Harrogate; Mr. G. Hobson Thompson, Buxton; and Dr. Christopher Vise, Tunbridge Wells. Chairman of Council: Dr. Alfred F. Street, Westgate. Honorary Treasurer: Dr. R. Fortescue Fox, London. Librarian: Dr. Harry Campbell, London. Honorary Secretaries: Dr. Septimus Sunderland, London; and Dr. Mouillot. Dr. W. J. Tyson (Folkestone) and Dr. A. F. Street (Westgate) were appointed scrutineers, and Dr. A. Morison and Mr. Ernest Clarke were appointed auditors for the past session.—The report of the council for the past year was received and adopted. The question of amalgamation with the Royal Society of Medicine was discussed, and it was resolved that the meeting approves the recommendation of the council that the society shall become in October next a section of the Royal Society of Medicine.—An ordinary meeting was then held, at which Sir James Barr (Liverpool) delivered an address entitled, "The Peripheral Circulation and its Treatment."

Reviews and Notices of Books.

Oxford Medical Publications: A System of Diet and Dietetics. Edited by G. A. SUTHERLAND, M.D. Edin., F.R.C.P. Lond. London: Henry Frowde and Hodder and Stoughton. 1908. Pp. 893. Price 30*s.* net.

THE subject of diet, both in health and disease, is one upon which it is most essential that the practitioner of medicine should be thoroughly well informed. A practical treatise on this subject should, therefore, always be welcome. Dr. Sutherland in his preface points out that until our knowledge of physiology is more perfect than at present the scientific basis of dietetics must be an unstable one; but that since patients must be dieted, practical experience, controlled by such scientific information as is obtainable, must be relied on. He has accordingly chosen his collaborators because of their special experience of the subjects entrusted to them, and the articles contributed by them represent their own views and practice, and not a compendium of the opinions of different authorities, although these are in many instances included and discussed.

Sir Lauder Brunton contributes an introductory chapter on general principles. The nature of various diets, the effects of cooking, the uses of condiments and stimulants, the processes of excretion and metabolism, are briefly considered. Dr. Harry Campbell follows with an interesting and learned article on the evolution of man's diet. From a study of the changes in diet in the Primates he separates certain periods, and traces the evolution of hunting, cooking, and eventually of cibiculture, and shows the effects these have had upon the nature, quantity, and condition of man's food materials. Dr. E. I. Spriggs gives a clearly written and scientific account of the physiology of digestion, absorption, and nutrition, which is more up-to-date than the usual chapter of this kind in works on dietetics. His description of the digestive processes includes an account of the various ferment actions and of the mechanisms by which they are brought into action, including the hormones. He also discusses the formation of the amino-acids as the final products of intestinal digestion and the manner of their metabolism, including their reintegration into tissue proteins. Dr. Spriggs also contributes a chapter on the results of experimental work on diet. The physiological heat values are given, the question of protein requirement is considered, and various diet scales are analysed. The chapter as a whole gives an interesting *résumé* of the scientific principles of dietetics.

Dr. Edmund Cautley writes of diet cures and special diets, of patent and proprietary foods, and of the invalid's dietary. The various special diets are described with their uses and with sufficient detail to render it practicable to prescribe them. He notes the treatment by butter-milk and by lacto-bacilline, and gives details with criticism of vegetarian, fruitarian, and other dietaries. His chapter on patent and proprietary foods contains a useful classification and gives analyses of the most important, many of which are quoted from THE LANCET. In regard to the invalid's dietary, he gives directions for the preparation of various food substances which should be very useful. The subject of the use of alcohol in health and disease is discussed in a critical and temperate manner by Dr. Harry Campbell, and his recommendations are practical and free from bias. The chapter on artificial methods of alimentation by Dr. Francis D. Boyd, containing full accounts of rectal feeding and of the subcutaneous administration of food substances, is one worthy of special note. The value of these procedures is critically analysed, and the results of special researches conducted by the writer are included. Dr. Claude B. Ker discusses diet in fevers. Special attention is given to the various diets which have been employed in enteric fever, and full details are included of the modification necessitated by the complications which occur, and also of the diet in convalescence. The diet in tuberculosis is dealt with by Dr. N. D. Bardswell and Mr. John Ellis Chapman. The general principles underlying the construction of diet scales for patients suffering from pulmonary tuberculosis are enunciated, and various diets are given with their caloric values, including special forms adapted to the requirements and resources of the leisured and working classes respectively. The diets adapted to various complications such as laryngeal tuberculosis, hæmoptysis, anorexia, and diarrhœa are also given.

Dr. A. P. Luff gives practical and explicit directions regarding the important subject of the diet in gout, rheumatism, and rheumatoid arthritis. Dr. J. Rose Bradford indicates the general principles for the differentiation of the different varieties of diabetes and for the choice of a diet best suited to each. The question of the degree to which carbohydrate foods may be permitted and the selection of the various articles of diet are carefully described. Obesity is discussed by Dr. Edmund Cautley. Numerous special diets are given in detail, and the chapter affords a useful study of the dietetic restrictions recommended in the treatment of this condition. The diet in arterio-sclerosis is dealt with by Dr. Harry Campbell. The difficult subject of diet in diseases of the stomach and intestines receives careful consideration in the two articles contributed by Dr. Herbert P. Hawkins, whose classification is convenient. Here the directions given in regard to the appropriate methods of feeding in gastric and duodenal ulcers, in mucous colic, and in constipation are all worthy of mention from their practical nature and from the clear and explicit manner in which they are set forth. Dr. W. Hale White gives an account of diet in diseases of the liver and pancreas, special stress being laid upon the best methods of feeding in cases of jaundice and of gall-stones. Diet in diseases of the lungs is described by the editor, Dr.

G. A. Sutherland, who devotes a considerable proportion of his article to a discussion of the use of alcohol in the treatment of pneumonia. He assumes that the commonest cause of cardiac failure in pneumonia is poisoning and paralysis of the medullary centre, and that alcohol is, in the majority of cases, a stimulant of that centre. He admits that these are assumptions, and states that the clinical experiences of many observers support them. The article on diet in diseases and disorders of the heart by Dr. W. J. Hadley, and that on diet in diseases of the blood and blood-forming organs by Dr. John M. Cowan both afford practical and explicit directions in regard to these conditions.

Dr. Rose Bradford contributes an interesting chapter on diet in diseases of the kidneys. The influence of diet upon renal activity and upon the character of the urine is carefully outlined, and stress is laid upon the importance of regulating the intake of salt in renal disease, as well as that of the proteins. In the diet of acute nephritis the use of milk and of salt-free foods is recommended, while fruits and fruit juices are permitted. In chronic nephritis the disadvantages of an exclusive milk diet in some cases are set forth, and some useful practical directions are given as to the employment of eggs and even poultry, meat, and fish. Similarly in the albuminuria which persists after an attack of nephritis and in the so-called functional albuminurias limitation of the dietary is deprecated. Dr. Bradford's article is thoroughly interesting and useful. Dr. James Taylor treats of diet in diseases of the nervous system, Dr. T. Colcott Fox of diet in diseases of the skin, and Dr. Harry Campbell of diet in old age.

The important subjects of the feeding of infants and children in health and of diet in the diseases of children are dealt with by Dr. G. A. Sutherland in a manner wholly admirable. Careful and full directions are given in regard to breast-feeding and artificial methods of alimentation. We note here that Dr. Sutherland recommends the use of an ordinary feeding cup with a large rubber teat attached to the end of the spout in preference to any form of feeding bottle, but we fancy that nurses could find a practical objection to this advice. An instructive article on diet in the diseases of hot climates by Sir Patrick Manson and Dr. C. W. Daniels concludes the volume, to which a useful index is appended.

This System of Dietetics is one we can commend as thoroughly practical, and one which fulfils the objects expressed by the editor in his preface. It gives the results of actual experience rather than of purely theoretical speculations, and it affords directions in regard to actual diet scales in a manner easy to apply.

The Faith and Works of Christian Science. By the Author of "Confessio Medici." London: Macmillan and Co. 1909. Pp. 242. Price 3*s.* 6*d.* net.

THIS excellent little book is written without doubt by a medical man who is at the same time a loving student of literature and of philosophy. In the preface he states that the recent publication of the books of Mr. Lyman Powell and Mark Twain on "Christian Science," and the growth of the Boston Emmanuel Church movement as described in "Religion and Medicine" (recently reviewed in our columns[1]), give evidence that in America the Church of Christ Scientist is passing from consolidation to disintegration. In the ensuing chapters the author discusses the various aspects of "Christian Science"—its philosophy, its attitude towards Christ, the reality of diseases and of pain; the testimonies of healing and the opposing testimonies, and the attitude of common-sense and of authority towards "Christian Science." The chapter on philosophy is written by one who knows something of philosophy, and who is therefore competent to show the extravagant vagueness and looseness of thought which Mrs. Eddy's followers in their ignorance believe to be genuine philosophy. Every first-year student of metaphysics will recall the exaltation and joyous wonder which pervade his being when he first learns of the unreliability of the senses, how the whole world appears to dissolve into a mist of unreality, how ineffably superior he feels to the man in the street who has never heard of Subject and Object nor considered Mind and Matter from the metaphysical standpoint. Every student of philosophy can detect Mrs. Eddy's failure to grasp the subject, how she is entangled in obscure phraseology which is unintelligible nonsense to the genuine student, but to the average mind appears pregnant with infinite meaning. We can understand its attraction for those who are ignorant of philosophical terms. As the author states (p. 25): "The old antagonism between the materialist interpretation of consciousness and the transcendentalist has mostly been upheld by the combatants who thought hard and used words with some regard for their meanings. Christian Science has got hold of the words; but not of the meanings."

In Chapter VI. the testimonies of healing which are quoted by the author have the customary vagueness, the absence of definite and authenticated medical diagnosis, which we are accustomed to find on endeavouring to trace the cure of a so-called organic disease by psychical means. Every practitioner knows the weird descriptions given even by patients of the educated classes of the diagnosis and advice given them by their previous advisers. These are not necessarily always false or foolish, for the medical man in seeking to explain to the patient has to employ non-medical terms, which may convey an erroneous idea of his meaning. The chapter on Opposing Testimonies is the most important in the book, for in it the author analyses from the medical standpoint several of the great cures claimed by "Christian" science, and shows how worthless they are from the point of view of truthful science, and also gives a list of 68 black cases, cases of failure, of injury, and of death due to "Christian Science," all of which were collected from various medical men within a few short weeks. In the chapter on Common-sense there is a strong plea for the children which should stir the heart of every parent. "Common-sense cries, For God's sake leave the children alone. ...... For their bodily safety children must believe in the reality of injuries, disease, and pain. ...... Is it fair to tell a child that pain is not real? ...... Christian Science says that she teaches children to be singularly fearless. The reader can decide the worth of this defence."

The writer, moreover, shows his breadth of mind by admitting frankly the field of usefulness occupied by "Christian Science" in helping to improve the lives of "a multitude of men and women. Outside the intense cases of nervous mimicry and neurasthenia ...... are cases innumerable, circle beyond circle, of pleasanter people, many of them blessed with lives of singular refinement, who are the better for Christian Science." They become improved in mind and body because they have, in this busy hurried age, learned how to rest, to be at peace. Mrs. Eddy has popularised by her wide organisation of teachers the great truth taught so long ago, the necessity of rest in the Infinite. That one truth will survive when her doctrines of self-assertion and negation of matter will have passed away, as all false doctrines do. "Christian Science" has had a wider popularity than the other rival mind-healing sects in America, simply because of Mrs. Eddy's power of organisation. Day after day the pupil has to read the new "bible" without question or discussion, has to listen to public readings of the same bible, also without discussion or comment. Gradually the pupil is, as it were, hypnotised; he cannot escape from "Christian Science" unless serious disease attacks him. But there are millions of equally happy, healthy, godly people who have attained to their happiness, health, and virtue by more charitable, humble, and truly spiritual means, by daily study of the true Bible, and true philosophy. Medical men of to-day have recognised the wisdom of dealing with certain harassed, restless patients by insisting on a daily time for quiet meditation and reading of selected books.

---

[1] THE LANCET, Feb. 13th, 1909, p. 469.

Every medical man should read this little book. In these pages of kindly wisdom and shrewd logic they will find answers to the questions so constantly put to them by patients who are inclined to substitute for faith in scientific therapeutics faith in every ignorant and self-seeking "mind-curer."

Surgical Diseases of the Abdomen: with Special Reference to Diagnosis. By RICHARD DOUGLAS, M.D., formerly Pro- [illegible] Surgery, Medical [illegible] Nashville. Second [illegible] by RICHARD A. BARR, B.A., M.D., Professor of Abdominal Surgery, Medical Department, Vanderbilt University. Illustrated by 20 full-page plates. London: Rebman, Limited. 1909. Pp. 897. Price 26*s.* net.

THIS is a practical text-book on an important subject. The thoroughness with which Dr. Douglas carried out the writing of the first edition necessitates few changes in the original text in the second. The text has been preserved practically intact and apparently no additions have been made to the bibliographical references at the end of the articles on the various subjects since 1903. The sections dealing with peritonitis, and especially tuberculous peritonitis, are particularly interesting and are well written; we should have appreciated, however, a fuller description of the advantages of vaccine-therapy in the case of tuberculous peritonitis, important work at which subject we know to have been done in America. Intestinal obstruction is also well dealt with, and the section relating to surgical interference in the case of perforating intestinal typhoid ulcer provides considerable food for thought, notwithstanding no reference to literature is put forward in the table of bibliography at the end of the section of a later date than 1901. In the sections dealing with penetrating and gunshot wounds of the abdomen and the different abdominal viscera respectively, we regret that no reference has been made to the reports, official and otherwise, relating to the South African war (1899–1902) and the Russo-Japanese war, the literature of which somewhat revolutionises the aspects of modern gunshot surgery caused by small-bore missiles when contrasted with the wounds inflicted by firearms of the nature of those used in previous wars. While several sections are devoted to pelvic organs and pelvic conditions, such as the bladder, uterus, ovaries, ectopic gestation, &c., no reference is made to any of the surgical diseases of the rectum, which is the more odd that in this section of surgery America is by no means behind the times.

The work is well illustrated and the type is good. The index is very satisfactory—always a matter of considerable importance in a large book of reference. We regret that more reference has not been made to recent work in abdominal surgery, but to those who have not read the previous edition we consider the work likely to be very useful, especially to medical practitioners who wish to have a full account of the diagnostic conditions that may require expert surgical assistance.

LIBRARY TABLE.

"The Modern Mother": a Guide to Girlhood, Motherhood, and Infancy. By H. LAING GORDON. London: T. Werner Laurie. 1909. Pp. 270. Price 6*s.* net.—The title of this volume is a little unfortunate. To the reviewer who has had to read many works on this subject it foreshadows either the unwholesome sentimentality or the mass of fads which so often ruins this class of handbook. Dr. Laing Gordon, however, takes a wholesome, simple view of the aim of womanhood, which is "to see a girl become a successful wife and mother …… it is impossible to set up a higher ideal, or a more natural or pleasanter object in life"; and the lines upon which his advice is directed are indicated broadly by his warning against the difficulties encountered in the modern maze of "scientific gymnastics, physical culture and anti-uric dietary, massage vibration," on one side, and "the simple life" on the other. On the subject of exercise lawn tennis is selected as the summer game *par excellence* for girls, and, in our opinion, open winter courts might be established in many good-class schools to the exclusion of hockey. Young girls, under 12 years old, should, in Dr. Laing Gordon's opinion, not be allowed to bicycle or only to ride under strict supervision. All Dr. Gordon's remarks on dress will not meet with complete approval; we fail to see the reason for his preference for knickerbockers over woollen combinations; the latter are much more readily washed and do not produce the same amount of ecthyma and allied forms of pyodermia which are often seen in quite "smart" schools. In considering the burning question of stays the author defends them as a working compromise; he maintains that they have their uses as a support and help to preserve graceful contours; he is quite alive, however, to their evils and abuses. His treatment of the point illustrates the general breadth and common-sense which distinguish the book. The chapters on marriage and motherhood are discreetly and well handled, and so are those on infantile hygiene. In the light of Mr. John Burns's recent diatribes against infant comforters, it is refreshing to find the criticism "that the sight of a comforter in a baby's mouth is invariably a sign of weakness of character in his protector." The "medical" chapters dealing with the diseases of childhood are admirably direct and simple and are not calculated to make mothers believe they are qualified specialists in children's diseases after their perusal. We should have liked to see a little more stress laid on the care of the eyes in childhood and a little closer detail as to the recognition of errors of refraction by parents. The worst chapter in the book is that on the mental and moral training in early childhood. In much of its composition there is undoubtedly what the immortal Charles Lomax would call "a certain amount of tosh."

University of Pennsylvania: Contributions from the William Pepper Laboratory of Clinical Medicine. No. 6. Philadelphia. 1907 and 1908.—This volume contains a number of reprints of important papers emanating from the workers in the William Pepper Laboratory. They are too numerous to mention individually although they are all of interest. Dr. David L. Edsall and Dr. Ralph Pemberton describe the use of x rays in three cases of unresolved pneumonia. They find rapid clearing up of the signs of consolidation. They are careful to warn us against using x rays where there is marked fever or other evidence of toxæmia, and they admit that the number of cases is too small to admit of any positive conclusions. The same authors contribute a paper on the General Toxic Reaction following Exposure to X Rays. Dr. William Pepper and Dr. Verner Nisbet give details of a case of Fatal Hæmolysis following Direct Transfusion of Blood by Arterio-venous Anastomosis. Dr. William R. Nicholson and Dr. Joseph S. Evans contribute an interesting account of the Bacteriology of the Puerperal Uterus. They find that the uterine lochia are sterile in normal cases throughout the puerperium and that streptococci are never present within the cavum uteri without causing symptoms

Dr. Samuel M. Hamill, Dr. H. C. Carpenter, and Dr. Thomas A. Cope discuss the von Pirquet, Calmette, and Moro tuberculin tests in an interesting paper reprinted from the *Archives of Internal Medicine.* Dr. R. S. Lavenson gives an account of the post-mortem appearances in a case of congenital obliteration of the bile-ducts with cirrhosis of the liver. In opposition to the views of Dr. H. D. Rolleston, he regards the obliteration of the bile-ducts as the primary condition and the cirrhosis as a result of the consequent biliary stasis. He gives a useful bibliography. The same author contributes an exhaustive study of a case of aplastic anæmia, which he regards as a variety of progressive pernicious anæmia. Dr. Benjamin A. Thomas discusses the variability and unreliability in the determination of the opsonic index. He concludes that the percentage index of phagocyting leucocytes of Simon is of more value from the practical standpoint than Wright's phagocytic index. The character of the papers in this volume is of a high order, and it forms a valuable record of good original work.

Livingstone College Year-book, 1909.—The Year-book of Livingstone College for 1909 contains Rules of Health for Missionaries in the Tropics, drawn up at the instance of the Association of Medical Officers of Missionary Societies, and these contain, in a very small compass, information which is needed by all Europeans going to the tropics as to the preservation of their own health. These rules are absolutely up to date, based upon the most recent researches in the subject of tropical hygiene, and should prove of value. There is also a careful *résumé* of a year's progress in tropical medicine, including interesting particulars concerning the Sleeping Sickness Bureau, and the latest suggestions as to treatment. There are also notes on outfits, based upon the exhibit of outfits now being held at the Royal Agricultural Hall, entitled "Africa and the East," news from Livingstone College students, showing the way in which medical and surgical knowledge gained at the College has been put to practical effect, and some interesting cases.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. II., No. 7 (May, 1909). London: Longmans, Green, and Co. Price 7*s.* 6*d.*—The Section for the Study of Disease in Children, which opens this number, contains a valuable paper by Mr. N. Bishop Harman on the Effects of School Life upon the Vision of the Child, founded upon an extensive experience of the ocular defects of elementary school children in London. Mr. Harman's conclusions are more hopeful than have been recent pronouncements on the same subject. He considers that in general the eyes of London school children are in a very fair condition, especially in comparison with the reported state of the children's eyes in German schools. By far the greater proportion of visual defects are due to hypermetropia and its associated astigmatism, which the author shows reason for believing to be "the normal conditions of human eyes." He finds that myopia and the associated astigmatisms occur in less than 3 per cent. of school children. In refutation of the "First Study of the Inheritance of Vision and the Relative Influence of Heredity and Environment on Sight," recently advanced by Miss Amy Barrington and Professor Karl Pearson, Mr. Harman considers the incidence of myopic defects to bear a direct relation to faulty social conditions, such as overcrowding, lack of fresh air and sunlight, as well as to excessively "fine" school-work. He calls these defects the "manufactured" cases of bad vision. To the Neurological Section the same author contributes an account of the "Diaphragm Test" for Binocular Vision, which includes a simple but subtle method of trapping "monocular amaurotic" malingerers. Interesting case reports are contributed to this section by Dr. Wilfred Harris, Dr. G. de B. Turtle, Dr. T. Grainger Stewart, Dr. Gordon M. Holmes, and Dr. Leonard G. Guthrie. The Clinical Section is occupied with cases, including the interesting series of Mongolian idiocy which has been already described in THE LANCET. In the Dermatological Section Dr. H. G. Adamson publishes a photograph of a Mouse with Favus, and cases are reported by Dr. E. G. Graham Little, Dr. T. D. Savill, Dr. J. H. Sequeira, and Dr. A. Whitfield. The chief contribution to the Electro-Therapeutical Section is a description, which we hope to publish, of a Vulvo-vaginal Electrode for Ionic Medication, by Dr. S. Sloan. Mr. T. J. Bokenham and Dr. N. S. Finzi also write on Ionic Therapy, and Dr. Horace Manders describes a therapeutic apparatus for producing continuous oscillations of electricity. The Epidemiological Section is occupied with an important paper by Dr. L. W. Darra Mair, entitled "The Etiology of Enteric Fever in Belfast in Relation to Water-supply, Sanitary Circumstances, and Shell-fish," with a report of the discussion which it evoked. The paper deals with the facts and data contributed by Dr. Mair to the report of the Belfast Health Commission appointed by the Local Government Board for Ireland in 1907. His investigation dealt with the etiology of enteric fever in Belfast, and a very strong case was made out against sewage-polluted shell-fish as a chief agent in the local epidemiology of the disease. The report was discussed fully in THE LANCET last year at the time of its publication. The Laryngological Section is occupied exclusively with cases, and in the Medical Section Dr. O. K. Williamson records some clinical observations on the Influence of the Vessel Wall on (So-called) Arterial Blood-pressure Readings, including a detailed study of a series of cases which lead the observer to the conclusion that the resistance of the vessel wall may influence hæmomanometric readings to a marked degree. Other noteworthy papers in the number are by Dr. Harold Simms, who describes in the Odontological Section a bacteriological research on the Action of Formalin and Other Root Dressings in dental practice, and by Dr. J. Gordon Sharp, whose Experiments and Experiences, Pharmacological and Clinical, with Digitalis, Squill, and Strophanthus, occupy the pages devoted to the Therapeutical and Pharmacological Section.

THE LONDON COUNTY COUNCIL AND SCHOOL MEDICAL OFFICERS.—To fill the vacancy caused by the resignation of Mr. K. M. Hunter (quarter-time assistant medical officer in the Education Department), the London County Council has promoted Dr. F. C. Shrubsall assistant school medical officer at a salary of £150 a year, inclusive of travelling expenses. In consequence of other resignations a rearrangement of the staff of school medical officers has been effected, and in order to carry out the scheme of medical inspection approved by the Board of Education an advertisement has been issued for 26 assistant school medical officers.

SURREY COUNTY HOSPITAL: A NEW CONVALESCENT HOME.—Apropos of the announcement in our columns on Oct. 24th last regarding the gift of Mr. G. P. Shepherd of £10,000 for the purpose of building and endowing a convalescent home at Worthing for patients from the Surrey County Hospital, Guildford, the home was opened on the afternoon of June 18th by the Viscountess Midleton. Above the main entrance of the institution is an inscription stone bearing the following words: "The George Prentiss and Emilie Shepherd Convalescent Home, in connexion with the Royal Surrey County Hospital, Guildford." For reasons of health, Mr. Shepherd, an old Guildford resident, was unable to be present at the proceedings. The home has been constructed in accordance with all the latest hygienic and sanitary requirements and is situated on the eastern sea front of the town. It may be here mentioned that there is another seaside institution in connexion with the Surrey Hospital on the Sussex coast—viz., at Bognor. The Worthing home will be reserved for those recovering from operations.

THE LANCET.

LONDON: SATURDAY, JUNE 26, 1909.

Radio-activity and Cancer.

ANY facts which bear in any way on the question of the mode of origin of malignant disease cannot fail to be of great interest, and they may easily turn out to be of the utmost importance. In the Croonian lectures which Dr. W. S. LAZARUS-BARLOW has delivered before the Royal College of Physicians of London this month he has described a series of experiments which he has been making during the past two or three years on the radio-activity of various substances, and in this way he has thrown a light on the yet unsolved problem of the etiology of cancer. Dr. LAZARUS-BARLOW started with the sinister and deplorable fact that the hands of many of the workers in x rays, true martyrs to scientific zeal, have developed epitheliomatous growths, and it is clear that the x rays have in some way or another led to this appearance of malignant disease. The influence may have been direct, the rays directly causing the development of cancer, or it may have been indirect, the rays merely preparing the tissues for the action of some other truly causative agent. Supposing that the action is indeed direct, the question naturally arises whether the substances which are usually supposed to give rise to carcinoma are also radio-active. These substances are such as clay pipes and soot; and cholesterin also is credited with the power of starting a malignant growth. These and many kindred matters Dr. LAZARUS-BARLOW and his assistants have investigated. He tested the materials in part by their power of affecting photographic plates in the dark, and this property he has called skotographic, a name which is certainly very convenient, though purists might consider it not happily chosen, for photography meaning "writing or drawing by light," skotography should mean "writing or drawing by darkness," an inconvenient term for that form of actinography in which the rays are invisible.

Dr. LAZARUS-BARLOW shows that substances which are associated with malignant disease, such as cholesterin, have a high degree of skotographic power, while others, such as a clay pipe and paraffin, are devoid of it. He has also proved that certain tissues of the human body, such as liver and kidney, show skotographic action, while others, as the spleen and lung, do not; that this skotographic power is greater in the tissues of women, and that it increases on the whole with age is also demonstrated, and our reproductions of his skotographs support his contentions. Carcinomatous material has skotographic power, especially when taken from the bodies of women. The nature of this power possessed by the substances examined somewhat resembles that shown a few years ago to belong to wood and believed to be due to a chemical action, but the skotographic power is also allied to that possessed by recognised radio-active substances. Substances possessing radio-activity have also the power of discharging electroscopes, and Dr. LAZARUS-BARLOW's work indicates that by the use of recognised radio-active substances retardation of the rate of discharge of electroscopes occurs, though physicists may have some difficulty in accepting certain of these results. All forms of radio-activity have also been shown by these experiments to have both accelerating and retarding influences upon the development of the ova of ascaris megalocephala, and thus a new idea is started as to the power of certain tissues to influence the rate of development of animal cells. It follows that in radio-activity we have a possible solution of the phenomena of malignant disease. Radio-activity would suffice to explain the irregular mitoses of malignant new growths; it would explain the lessened formation of pepsin and trypsin in carcinoma, for it has been shown that the activity of these enzymes is much diminished by radio-active influence. It would explain the curability of some superficial cancers, for in many microbic diseases it has recently been proved that the agent producing a disease may be pre-potent in elaborating the remedy. This explanation of the origin of carcinoma would not be opposed to the existence of cancer houses, for some soils or building materials might contain sufficient radio-activity to give rise to carcinoma in successive inhabitants. The idea is not opposed even to a microbic view of the origin of cancer, for the only question would be whether the suggested agent is radio-active or not. It is not incompatible with COHNHEIM's theory of embryonic rests or VIRCHOW's theory of mechanical irritation, for the radio-activity would be the underlying force required by each. Attempts to cause cancer by radium and other radio-active substances have hitherto been unsuccessful, though it has been clearly shown that an irregular overgrowth of epithelial cells may be thus produced.

We have found these lectures replete with interest. They record the results of innumerable observations and of an immensity of work. They shed fresh light on an intensely difficult problem, and they supply us with new facts in physics and biology that may one day bear much fruit. Whether we have here the true solution of the mystery of cancer is, however, another question. These observations, numerous as they have been, need repetition and extension, but they will always remain a proof of the excellent work done in the laboratory of the cancer department of the Middlesex Hospital. We appreciate highly the energy, accuracy, and skill shown by these investigations, we value the many new facts brought forward, and we anticipate great results from these investigations into the radio-activity of tissues, whatever may be the outcome of the researches when directed particularly towards affording a solution of the origin of cancer. To the lectures themselves we must refer our readers for a full account of the experiments performed and of the arguments advanced; for it is impossible to summarise them satisfactorily, while Dr. LAZARUS-BARLOW's own record is an extremely lucid piece of writing. Suffice it here to say that every step in the investigation appears to have been taken with the greatest care, and the only doubt is whether the facts deduced can bear the burden laid upon them. The experiments are apparently to be continued, and we must postpone till the investigations are complete any definite decision as to the adequacy of the explanations which are offered for the various phenomena observed; for the work accomplished and the manner in which it has been done we have nothing but praise.

Oral Sepsis.

THE pathological importance of the mouth has been appreciated at its proper value only of late years, when several diseases have been recognised as arising from micro-organisms breeding therein, and it is not improbable that the future will add greatly to the list of the morbid processes which may be attributable to oral sepsis. We are led to this reflection by the perusal of two papers appearing in this issue of THE LANCET by Dr. G. I. STEWART and Mr. L. A. PARRY respectively. That the conditions obtaining in the mouth are pre-eminently suitable for the nurture and growth of micro-organisms is now so universally allowed that we need do no more than enumerate the main points in the briefest manner. In the mouth we have a cavity to which entrance of micro-organisms from without is unimpeded. Every mouthful of food or drink or air that is taken may add greatly to the number of any microbes present, when the conditions of the cavity in conformation, temperature, and moisture favour rapid multiplication. So anfractuous a receptacle provides numberless hiding places where colonies of bacteria can lurk unmolested and increase rapidly. The spaces between the teeth offer suitable breeding-places, while cavities of their substance or pockets due to retraction of the gums add to the amenities offered to micro-organisms. The irregular surface of the tonsils plays its part, and all the conditions alike bring it about that numberless stray particles of food should be left behind in the oral cavity after swallowing, providing an enormous supply of decomposable material. The abundant supply of moisture, so necessary for the growth of most bacteria, has a weak alkaline reaction which also favours decomposition; and the temperature, which in the parts more exposed to air currents is several degrees below that of the body, in the more recondite positions reaches the body temperature, providing changes of climate suited to the constitution of a very large number of visitors. We need not therefore feel any surprise when we are told of the extensive flora present in the mouth: it is extensive even in the civilised man who devotes attention to the cleansing and care of his teeth, but among what is still the vast majority of people who never clean the teeth and whose mouths contain carious stumps this flora is oppressively luxuriant. Here it is, indeed, surprising, not that many septic processes, near and distant, may follow oral sepsis in such cases, but that life in so many instances continues almost undisturbed by processes going on in the gateway of respiration and digestion.

The question naturally arises, Has nature made no provision to cope with this enormous bacterial invasion? The answer is that some prophylactic measures have been taken; the adenoid tissue which forms abundant masses in the tonsils and lines also the upper part of the pharynx is apparently intended to intercept and destroy both bacteria and their products coming from the mouth; and the frequency with which this lymphoid tissue is inflamed testifies to the need for its presence. The mechanical cleansing of the mouth, that resulting from a natural diet, is also not to be despised. When hard food is taken into the mouth and chewed it removes mechanically many of the micro-organisms of the mouth, while soft, pulpy foods, so dear to the palate of modern man, favour the accumulation of decomposable material in the mouth. In the savage state, as in the lower animals, carious teeth are rare; opinions differ as to the reason why civilisation is followed by carious teeth, but the fact remains that caries appears to be much commoner in civilised communities than among the less advanced races. There are three methods by which this abundant microbic invasion may cause disease. In the first place, by direct extension the germs invade the gums, the tongue, and the cheeks, and extend into the neighbouring cavities of the pharynx and nose, setting up inflammation in the mucous membranes and in the deeper structures, and also involving the lymphatics and the glands. Not less important is the infection liable to be produced by aspiration of organisms into the respiratory tract, for thus are set up many forms of laryngitis and tracheitis, as shown in the paper by Dr. STEWART; and in the same way, though more rarely, is caused the aspiration pneumonia, so striking and fatal a complication of operations on the mouth. There is yet a third way in which an oral sepsis may invade healthy tissues, and that is by absorption, either directly from the mouth or after swallowing; and many general conditions, formerly of very obscure ætiology, seem now to be explicable as arising from the absorption of toxic products formed in the mouth. Great and important though these septic processes in the mouth may be in ordinary circumstances, they are of especial importance in connexion with operations on the mouth and its adjoining cavities. Time was when surgeons proceeded to remove a tongue or excise a portion of a jaw without having paid any regard to the condition of the mouth. It is surprising that in many cases no obviously harmful results followed these operations, even though the condition of the mouth may have been septic in the extreme, but in only too many instances a septic pneumonia or a general infection has led to a fatal termination.

The case under the care of Mr. PARRY in which acute mastoiditis and later cerebellar abscess followed and evidently resulted from an operation for the removal of tonsils and adenoids is instructive. The operation of removal of adenoids is now looked upon as a very harmless operation, but septic complications are probably less rare than is usually imagined. With sepsis of the mouth present even slight operations on the mouth or in its neighbourhood may be followed by harmful results. The greatest attention should therefore be paid to the condition of the mouth in all such operations, and even in operations on parts farther off. It is now being recognised that oral sepsis militates greatly against operations on the stomach and intestines, and care as to the condition of the mouth is likely to be followed by better results. In all obscure morbid conditions arising in any part of the body it is well to take into consideration the condition of the teeth, for in oral sepsis we may find the explanation of many morbid processes, and in its removal we may find the simplest and most satisfactory method of treatment. On the condition of the mouth much of the health of the nation depends, and it is a sign of awakening wisdom among us that the care of the teeth of our children is now to share public attention with the curriculum for their instruction.

◆

The Medical Inspection of School Children: By Whom Should it be Carried Out?

WE have referred in many recent issues of THE LANCET to certain circumstances in connexion with the medical inspection of school children, dwelling firstly on the situation at present existing between the metropolitan hospitals and the London County Council, and secondly on the possibility of the institution of school clinics being recognised as the preferable method among several methods for the carrying out of any treatment following upon inspection. We wish this week to look at another phase of a complicated and difficult question, rural districts being now under consideration rather than the metropolis or great urban communities. The duty of inspection has been delegated to local administrative bodies by the State, and medical men ought to be ready to consider the several proposals which have been, and are being, made for carrying out the work both of inspection and treatment, remembering always that the prime interest of the State is the health of the community rather than the internal policy of any profession. The growing disposition on the part of the State to monopolise for small remuneration the services of medical men for this purpose is raising difficulties which can by no means be ignored, and these difficulties appear to be increasing rather than diminishing day by day. There is, for example, a distinct tendency on the part of the education authorities to procure the inspection in question by the instrumentality of young medical men who are required to devote their whole time to the duties of their office, and there are, of course, many reasons which can be adduced in support of this practice. Amongst other things it makes for unity of method in the several schools of the district, and prevents, or should prevent, friction which might in some cases not inconceivably arise amongst the local practitioners were the medical inspection carried out by one of their number. There are, however, objections which may be urged against these whole-time officers, and one of them is the fact that they are not and cannot get into touch with the children and the parents in a manner which might be the case were the work divided amongst the local practitioners, while the consideration that their term of office is likely to be transient lends additional force to this contention. Yet as things are at present arranged by the Local Government Board and the Board of Education there are reasons why the actual inspectorial work should in some cases, as, for instance, in a county area, be carried out by the local medical officer of health acting under the supervision of the county medical officer of health, and this is the arrangement which has actually been introduced on the recommendation of Dr. F. E. FREMANTLE, the county medical officer of health, in the county of Hertfordshire. Perhaps the strongest argument in favour of this arrangement is the desire on the part of the two Government departments concerned in the health of the children that there shall be cordial coöperation between the school medical officer and the local medical officer of health, both of whom are given jurisdiction in the schools in the matter of control of infectious disease. It is the wish of both Government departments that medical inspection "should be carried out in intimate conjunction with the public health authorities and under the direct supervision of the medical officer of health," and that "as far as is practicable the school medical service should be uniform with the public health service." We quote the words of a recent circular of the Board of Education.

Such cooperation ought not to be difficult of achievement if both the school medical officer and the medical officer of health possess elementary administrative tact, although each of these officers is given specific administrative functions in connexion with both the schools and the scholars. The medical officer of health has already to report upon the sanitary conditions of the schools as well as upon the action taken in relation to the health of the scholars and for preventing the spread of infectious disease, while the Board of Education, in its circular No. 576, refers to the objections to dual jurisdiction in the sanitary control of school premises and the notification and prevention of the spread of infectious diseases, in which directions the duties of the medical officer of health and of the school medical officer necessarily and obviously overlap. The Board of Education goes on to point out that "if these duties are to be effectively carried out the interest and activities of the school medical officer must extend over the whole external environment of the child," adding that "efficiency and economy require therefore an organic relationship between the daily work of the school authority and of the authority responsible for the administration of the wider branches of public *health*" There is no doubt as to the necessity of this organic relationship, and in certain instances it may perhaps be best provided for by the appointment, as in Hertfordshire, of the district medical officers of health acting under the superintendence of the county medical officer. But it seems to us that *there* are *many* circumstances in which this arrangement would not be so desirable as one by which the actual inspection was carried out either by a whole-time officer or officers, or by local medical practitioners, whether medical officers of health or not. When the local medical officer of health is also in private practice there might be professional objections to his becoming the school medical officer, objections which would tend to be emphasised were the treatment of diseased conditions by the education authority to become at all general. We are not, now, discussing the matter of treatment; but this is the all important side, and the machinery of inspection will be valueless unless it is put into action with a view towards treatment.

Notwithstanding the opinion expressed by the Board of Education as to the undesirability of dual control, such dual control must obtain in certain particulars, and therefore the officers concerned in such control, being in many instances officers of the same authority, must work harmoniously together much in the same fashion as the medical officer of health, the surveyor, and sanitary inspector have had to do for very many years past. Each of these officers has jurisdiction over certain matters in common, and the arrangement is one which is not without some advantages. One important consideration in favour of giving the actual medical inspection of school children to local medical officers of health in certain instances is that by so doing a part-time medical officer of health may be converted into a whole-time officer, an arrangement which to a great extent avoids the professional objections with regard to medical inspection which have already been referred to. But in so far as the work of inspection is concerned, we trust that the claims of those practitioners who are not also medical officers of health will not be overlooked, as from their local knowledge of the children and of their parents and their homes they are the most likely persons to be of service to the State in promoting the health of the rising generation.

Annotations.

"Ne quid nimis."

THE PRICE OF RADIUM.

IT is to be hoped that some other source of rays having the same curative properties as the radium rays will soon be discovered, having regard to the extreme rareness and costliness of this extraordinary element. We do not despair that some such discovery will be made, especially in view of the fact that recent investigations have led to a differentiation of ray from ray, some proving to be irritant in their nature, while others are healing. The x rays had not long been tried in therapeutics before it was found that a skin irritation beyond the power of remedies was set up; later a means was found of filtering the rays from their irritating component, so that all danger in their application can be avoided. It is therefore conceivable that as the work of analysis or differentiation of rays progresses the exact radiation that is required in the treatment of disease will be found. Next, this method of analysis applied to radiations given off by various electric discharges may lead to the separation and concentration of an identical radiation, a discovery which will make us independent of a radium supply and which will open up a vast new domain in the treatment of disease, or so it appears from the promises of recent pathology. This week it was announced that a contract for the supply of about a quarter of an ounce of radium bromide had been placed with a mining company owning a pitchblende mine in Cornwall. The price is said to have been fixed at about £114,000 per ounce. The radium is to be presented by Lord Iveagh and Sir Ernest Cassel to the Radium Institute. It is stated that the radium will be separated from its ore by a firm in Germany under the superintendence of its chemist. This last announcement will come as a disappointment to most English people, and doubtless it will lead some to believe that the work of separating radium from pitchblende is not amongst the attainable achievements of the English chemist. Not long ago an English chemist visited a pitchblende mine in Cornwall, and was informed that the ore after powdering was sent direct to Germany because "the English chemists did not know how to treat it here." We are certain that is not the case. On being asked whether radium was made from it the miners did not know, but stated that uranium had been used in making ornamental glass for a good many years. It is probable, therefore, that when radium was discovered in Cornish uranium ore (pitchblende) the workers who employed it for tinting glass turned their attention to the rare element, and finding it present doubtless entered into further contracts which would make the task of extracting radium a profitable undertaking. If this is what has happened the incident seems to us to give further proof of the opportuneness of the Prince of Wales's warning to England to "wake up," and it is a queer coincidence that the illustrative circumstance should have occurred in his own duchy.

THE MEMORANDUM OF THE DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE ON CHRONIC TYPHOID CARRIERS.

WE have received a copy of an important Memorandum prepared by the Director-General of the Army Medical Service, and presented to both Houses of Parliament, on the difficult subject of the Transmission of Enteric Fever by the "Chronic Carrier." We commented upon one side of this question from the point of view of civilian practice in THE LANCET of June 19th, p. 1770, and pointed out the difficulties in keeping watch after convalescence upon the patients who have suffered from the disease with a view to the discovery and treatment of those who are carriers of the bacilli. We further published an interesting case recorded by Dr. P. J. Cammidge, in which there was evidence of discharge of typhoid bacilli by the fæces 10 years after recovery from the disease. The Director-General, in his memorandum, gives an interesting *résumé* of the history of the discovery of the existence of "typhoid carriers," and of the means taken by the Government of India to discover and isolate them from the troops. On the recommendation of a committee specially appointed to consider the question Naini Tal depôt was reserved for patients convalescent from enteric fever, and bacteriological investigations were carried out, with the result that during 1908 several chronic carriers were detected and subsequently invalided to England. Since all attempts to render such patients free from the bacilli by medicinal treatment, such as by the administration of salol and urotropine, have proved unsuccessful, the Army Medical Advisory Board deputed a subcommittee to investigate other methods of treatment. They found that the cases fell into four groups—viz., pure intestinal cases, urinary cases, intestinal cases with symptoms of inflammation of the gall-bladder, and mixed intestinal and urinary cases. In the pure intestinal cases it was thought that lactic acid bacilli might possibly serve to disinfect the gastro-intestinal tract, and this form of treatment was employed in two cases specially selected for that purpose. In one of these the treatment has apparently been successful; in the other, although the Bulgarian bacilli were well established in the alimentary canal, typhoid bacilli continued to be passed, but in diminished numbers. It is of interest to note in this connexion that Professor Drigalski, in conjunction with Professor Fraenkel, has obtained apparently successful results from this treatment in two cases. In regard to the other classes of typhoid carriers it was obviously improbable that the lactic acid bacilli could effect any great improvement, and it was decided to attempt to treat these cases by means of vaccines with the view of increasing the protective reactions of the body towards the bacillus. It was found that on employing in these cases the stock vaccine used in the prophylactic inoculation against the disease the protective substances were increased, but the excretion of bacilli was not arrested. The elaboration of protective substances appears to be related to the virulence of the strain of typhoid bacilli which has infected the body, and a vaccine prepared from a comparatively non-virulent strain does not appear to be very effective. In future it is intended to prepare a vaccine from each patient's own organism. Sir Alfred Keogh's memorandum is an important contribution to the study of the problem of carrier cases, and although the results so far obtained are inconclusive they are sufficiently encouraging to warrant further work upon the same lines.

POST-MORTEM CÆSAREAN SECTION.

THIS operation is undoubtedly one of great antiquity, although it is difficult to state at what period of time in the world's history it was first performed. The *lex regia* of Numa Pompilius, by which it was enacted that in the case of a pregnant woman near full term dying undelivered the body should be opened immediately after death and the child extracted, shows that it was known to, and practised by, the Romans. That post-mortem delivery was recognised in ancient mythology is suggested by the legends surrounding the birth of Bacchus and of Æsculapius, and renders it probable that its first origins are to be sought at a very early date. Rosenbaum is, indeed, of opinion that the operation was practised probably by the professional embalmers among the ancient Egyptians. Subsequent to the date of the *lex regia*, numerous ordinances were passed for the same purpose, but it would seem that the procedure fell into disrepute possibly on account of the bad results obtained as regards the life of the children. With the spread of Christianity and of the rite of baptism, which gave to the life of the unborn child an increased worth, the operation again came into favour, and in the first half of the eighteenth century Pope Benedict issued a precept in which the indications for, and the precautions to be observed in, its performance were duly set forth. As Hubert remarks, the Roman Catholic Church reproduced the injunction of the *lex regia* in the following decree of its ritual: "Si mater praegnans mortua sit, fructus quam primum caute extrahatur." At the present day post-mortem Cæserean section holds a definite place in the medical art and should undoubtedly be practised in all cases in which the chance of delivering the child alive is present. In some countries indeed, for example, in the German States of Bavaria, Würtemberg, and Saxony, the *lex regia* is still in force. In France and England the matter is left to the discretion of the attendant physician, and as a natural result in these countries the operation is undertaken very infrequently. The reluctance of many obstetricians to perform it is explained when we study the results shown by the older statistics; thus of 299 operations of this nature performed up to the year 1888, in only 19 cases were the children extracted alive and only 5 of these survived. Modern statistics are, however, much more encouraging—for example, of 14 cases collected by Bauer, 10 children were born alive, and of 28 cases collected by Dicke during the years 1875 to 1903, 28 children were delivered alive, of whom 19 survived. It must be remembered, however, that these figures are probably unduly favourable, since only successful cases are likely to be published. The chance of the child surviving will necessarily depend a good deal on the cause of the mother's death. The researches of Breslau and Runge have demonstrated that the fœtus is most likely to survive for some length of time after the death of the mother when this has taken place suddenly. In cases of high fever or of acute septic poisoning the fœtus not infrequently dies before the mother. The accounts of cases in which children are said to have been extracted alive from the uterus even after the burial of the mother, belong to the realms of fiction. Of this description is the story of François de Civile, who on great occasions signed himself "trois fois enterré et trois fois par le grâce de Dieu resuscité," and who is said to have been delivered by a Cæsarean section performed on the exhumed body of his mother. The most recent observations point to the likelihood of obtaining a living child after a longer interval of time than 20 to 25 minutes after the death of the mother being extremely small. In two recent cases recorded by trustworthy authorities, living children were extracted 19 and 17 minutes after the sudden death of the mothers. The suggestion that in order to minimise the risk to the child the operation should be performed on dying patients before a fatal issue actually results has found favour recently amongst various obstetric writers. This suggestion is one, however, of considerable antiquity, and was put forward by some of the older Italian writers, who discussed the advisability of the operation in the moribund state before death actually occurred. A number of modern cases of this kind have been recorded with a good result to the child. The difficulties in coming to a decision in such a condition will naturally be even greater than in the case of a patient who is certainly dead, and this procedure is consequently hardly ever likely to be practised except in a hospital. On the other hand, the performance of a post-mortem Cæsarean section may fall to the lot of any practitioner, and it is essential that he should have clearly in his mind the conditions which would render such an undertaking justifiable. These may be postulated shortly as follows: that the child should be viable and alive, that not more than 20 minutes should have elapsed since the death of the mother, and that the possibility of a rapid delivery by the natural passages should be out of the question. An interesting case in this connexion recently has been the subject of a coroner's inquest in the town of St. Laurent in Canada. A woman suffering from an abscess in the brain died during labour, and at the order of the priest in attendance a midwife performed post-mortem Cæsarean section, it is said with a razor, and extracted a living child who survives. The matter naturally occasioned a good deal of comment in a small town, and in view of the rumour which prevailed that the woman was not dead at the time the operation was performed the midwife was held by many to have committed murder. A post-mortem examination, however, cleared up the cause of death and all the parties concerned were exonerated. The performance of such an operation by anyone but a properly qualified medical man, especially in a case in which the patient was not dead at the time of its performance, might well expose the persons concerned to a charge being preferred against them of manslaughter, if not of murder.

ANNUAL EXHIBITION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE affairs of the Royal College of Surgeons of England are usually conducted in the quiet and well-ordered manner characteristic of our older institutions, so that events of considerable interest to the medical public may pass by unobserved. Every year on the day of election to the Council and the two succeeding days—July 1st, 2nd, and 3rd of the present year—all the specimens that have been presented or purchased or prepared for the Museum during the previous 12 months are placed on exhibition in the Council Room of the College, and give those who are engaged in active practice an opportunity of seeing in a concrete form an epitome of recent advances in surgery and in morbid, human, and comparative anatomy. The additions for the present year, some 380 in number, form a small museum in themselves, and represent gifts and purchases from all parts of the world. Those interested in the teeth and palates of primitive races will have an opportunity of examining a series of 83 crania of a primitive tribe of negroes obtained from a remote part of the Congo Free State. Mr. Rickman J. Godlee has presented a series of casts illustrating the cases of torus palatinus recently described by him. Mr. Shattock's preparations to show the manner in which fat deposits are made in various members of the vertebrate form an instructive series. Through Mr. T. P. Legge a specimen has been obtained from Western Australia to exemplify the operation of infundibulation practised by the aborigines of that part. Of the 90 specimens added to the pathological and teratological series, there are several of exceptional importance, and all of them show some new feature of diseased action.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

As will be seen by a notice in another column the annual meeting of this association, which is to be held in the very centre of London—that is to say, the Guildhall—will include a conference of the Poor-law Medical Officers of England and Wales upon the recent reports of the Royal Commission on the Poor-laws and Relief of Distress. It is particularly hoped that as many Poor-law medical officers as possible will attend this conference, for three of the Royal Commissioners are to be present, and the papers to be read are practical. It is probable, therefore, that the discussion which will ensue will deal with the highly important subject matters in a valuable way, and that much light may be shed on the difficult question of the administrative methods necessary to amend our existing system of medical relief.

EXCESSIVE URBAN MORTALITY IN IRELAND.

THE relatively high rate of mortality that prevails in the urban population of Ireland has scarcely received the attention that the subject deserves. The returns issued by the registrars-general for the several parts of the United Kingdom show that while the death-rate during last year did not exceed 13·8 and 15·2 per 1000 respectively, in London and Edinburgh, it was equal to 23·0 in Dublin City and to 21·5 in its larger registration area. This excessive urban mortality was not, however, confined to Dublin. It appears from the Annual Summary issued by the Registrar-General for Ireland, that the annual death-rate during the 53 weeks of last year, in 22 of the principal urban districts of Ireland (including Dublin), was equal to 20·2 per 1000, whereas the death-rate during the same period in 76 of the largest towns in England and Wales (including London) did not exceed 14·9. The rate of urban mortality in Ireland shows a marked excess, moreover, not only in comparison with the rate of urban mortality in England and Scotland, but also when compared with the mean rate of mortality in the whole population of Ireland. The above-mentioned death-rate of 14·9 per 1000 last year in the 76 large English towns exceeded the mean death-rate in the entire population of England and Wales by but 0·2 per 1000; whereas in Ireland the mean rate in the 22 urban districts exceeded the rate in the entire population of Ireland by no less than 2·5 per 1000. This marked excess of urban mortality in Ireland, whether compared with rates of urban mortality in other parts of the United Kingdom, or with the death-rate in the entire population of Ireland, calls for full and careful investigation. It is a well-known fact, to which special attention has been drawn in connexion with old-age pensions in Ireland, that the Irish population is abnormal as regards its age-constitution, containing as it does an undue proportion of elderly persons, the result of the long-continued emigration of young adults. The crude annual death-rate in Ireland was equal to 17·7 per 1000 both in 1907 and in 1908; but corrected for this exceptional age-constitution on the hypothesis of an age-constitution identical with that prevailing in England and Wales, the Irish death-rate in each of those years is reduced to 16·1 per 1000. This corrected rate, however, compares unfavourably with the death-rate in England and Wales, which did not exceed 15·0 in 1907 and 14·7 in 1908. The Irish returns unfortunately do not afford the means for correcting the Irish urban rate of mortality for the abnormal age-constitution of the urban population, but, as the age-constitution of urban populations is invariably conducive to a lower rate of mortality than the age-constitution of rural populations, it may safely be assumed that the excess of mortality in the Irish towns, measured by the crude death-rate, is understated. The fact, therefore, that the mean uncorrected death-rate in the 22 Irish town districts during last year exceeded the death-rate in the whole of Ireland by 2·5 per 1000, or more than 14 per cent., affords conclusive evidence of unsatisfactory sanitary condition in the towns, calling for more efficient sanitary administration.

THE PROPHYLAXIS OF YELLOW FEVER.

IT cannot be said that the specific germ of yellow fever has yet been discovered, but there is a general consensus of opinion that it is an ultra-microscopic organism which defies detection by the present means at our disposal. Based, however, on the discovery that the transmitting agent of the disease is a mosquito, the Stegomyia fasciata (or calopus as it is termed by American experts), the mode of spread of yellow fever and its prophylaxis have been fully and carefully worked out during the last few years. Dr. G. M. Guiteras, who has taken a conspicuous part in this work, has recently prepared a pamphlet on the "Prophylaxis of Yellow Fever," which has been issued by Surgeon-General W. Wyman, chief of the United States Public Health and Marine Hospital Service, as Bulletin 17 of the Yellow Fever Institute. In this pamphlet Dr. Guiteras sets out the principles on which prophylaxis of the malady is based. He emphasises the great importance of early diagnosis of this disease with a view to immediate notification, since it is a well-established fact that the stegomyia can only become infected by biting a yellow fever patient some time during the first three days of the illness, but not afterwards. It is therefore necessary at once to protect the patient from the bites of non-infected stegomyiæ during those first three days, and afterwards to secure the protection of healthy persons from the bites of infected insects. It is admitted that early diagnosis is in many cases extremely difficult, and for this reason Dr. Guiteras urges that all cases of febrile disturbance, the cause of which cannot be satisfactorily traced in localities where yellow fever has appeared, should be regarded, at all events for the first three days, as true yellow fever, and properly protected against the bites of mosquitoes. Dr. Guiteras places great importance on educating the public as to facts concerning yellow fever and the way in which it is spread, so that their help may be given in the measures directed against the transmitting agent. He points out that if war against mosquitoes generally were declared, not only would the diffusion of yellow fever be checked but also that of malaria. All important facts as to the transmission of the malady by mosquitoes should be taught in public and private schools as well as in colleges in those areas where yellow fever is liable to appear. Children should be taught to dread a mosquito as they now do other insects. Public opinion should be so guided as to make it regard the mosquito, not only as a disagreeable pest, but also as a very dangerous one. All collections of water should be abolished or covered with oil, and all cisterns should be screened securely with fine-meshed metallic gauze. Regular and systematic house-to-house inspection should be carried out weekly if possible to see that no "water containers" exist capable of harbouring mosquito larvæ. The use also of small fish in collections of water which cannot otherwise be dealt with is recommended. Lastly, the removal of all unnecessary obstructive vegetation and the screening of doors and windows of dwellings should be carried out in infected areas. The complete extermination of mosquitoes, it is admitted, is hardly practicable, but relative extermination is well worth attempting and is likely to diminish the danger. In times of serious epidemics of yellow fever Dr. Guiteras would go so far as to invoke the aid of "martial law," since he regards the present powers available under the Republican Government to be inadequate to secure house-to-house inspection and compulsory removal of all cases to hospital. With "martial law" to support the health officials, he contends that the prophylactic measures which he advocates could be better enforced in every detail, and outbreaks of yellow fever would thus be more effectually controlled. In connexion with Dr. Guiteras's recommendations it is interesting to note that in most of our own West Indian colonies much the same measures are now being, and for some time back have been, successfully enforced. From a letter quite recently written to the *Times* by Sir Robert Boyce, who had been sent to the West Indies to advise the local governments respecting a threatened epidemic of yellow fever, we learn that pupil teachers, sanitary inspectors, and others are now being trained by means of lectures, demonstrations, and health primers to take part in a determined effort to rid these colonies of mosquito-carried disease. It is now a punishable offence to harbour mosquito larvæ upon the premises, and already a considerable number of convictions have been secured with fines varying from 1*s.* to 40*s.* A careful study is being made of the local breeding-places of mosquitoes, and also investigations as to the natural enemies of mosquito larvæ. One of these enemies has been found in the small fish named "millions," quantities of which are now being exported to other tropical countries on this account. Both Dr. Guiteras and Sir Robert Boyce are convinced that if the measures above indicated were effectually and persistently carried out, yellow fever would not often trouble those fair and fertile regions in which it so often appears, to the legitimate alarm of the inhabitants and the detriment of trade and commerce.

FALSE ECONOMIES IN THE ROYAL ARSENAL HOSPITAL.

Woolwich, or at all events that very large portion of the residents who are connected with the Royal Arsenal, is seriously disturbed by a rumour that the medical department of the Arsenal is to be cut down—presumably to save expense to the War Office. Some years ago the number of medical officers was increased from three to four, and the small hospital, which had been almost exclusively used for accident cases occurring in the works, was added to, and surgical cases of all kinds occurring among the employees were admitted and operated upon, greatly to the advantage of the men, as there is no general hospital in the neighbourhood that can be counted upon as certainly available. The Woolwich and Plumstead Cottage Hospital on Shooter's Hill has only a very small number of beds, although it is fully equipped for the most serious operations. At Greenwich, though there is, besides the Seamen's Hospital, the Miller Hospital, the accommodation is still too limited, and consequently the Arsenal employees have greatly valued the opportunity afforded them of surgical aid within the walls of the Arsenal itself. This accommodation is now, it is understood, to be put an end to, only cases of accident while at work or exceptionally urgent ones, such as strangulated hernia or acute appendicitis, being admissible. The number of medical officers is to be reduced to three and further economies will be effected by the reduction of the nursing staff. Henceforth, therefore, a workman suffering from hernia, varicose veins, chronic appendicitis, fistula, or tumour, instead of being operated on in the Arsenal hospital, where there are always expert military surgeons able and willing to relieve him, must go to swell the numbers already waiting for admission to Guy's or some other London hospital. We trust that the Government will pay more heed than it seems inclined to do to the opinions of its own officials in Woolwich, and will recognise the tragedies which may follow on any cheeseparing in respect of the surgical equipment of the Arsenal.

ABDOMINAL ARTERIO-SCLEROSIS.

Only within recent years has the fact been recognised—principally in consequence of the work of German observers—that arterio-sclerosis of the abdominal arteries may cause distressing abdominal symptoms, an abdominal analogue of angina pectoris. This fact is important, for abdominal arterio-sclerosis is not uncommon, and when it produces symptoms these are misunderstood and regarded as due to gastric and intestinal affections. The diagnosis is not difficult if the practitioner bears in mind the possibility of such a condition; if he does not, a mistake is inevitable. In the *Journal of the American Medical Association* of June 5th Dr. H. L. Akin has pointed out the frequency with which the symptoms of arterio-sclerosis in the abdomen are regarded as due to gastric disorder and has reported a number of cases. A stockman, aged 56 years, who had enjoyed good health, "began to have trouble with his stomach." He took only two meals a day—a hearty dinner and supper. In the morning he felt well, but after dinner or supper if he walked a quarter or half a mile he experienced a feeling of fulness in the epigastrium and pain under the ensiform cartilage running down the left arm. He felt oppressed as if he could not breathe and must stop for a time. On stopping he belched up much gas and then could proceed without further trouble. If he sat still for half an hour after meals he generally had no symptoms. If he drank much fluid with his meals, especially ice-water or tea, he generally had an attack. His bowels acted regularly. He was a large meat eater and was subject to attacks of gout about every six months. The aortic second sound was accentuated; the pulse was 90 and of high tension. The urine contained a little albumin, but no casts. The acidity of the gastric juice was normal. As this was the first case of the kind which Dr Akin observed he regarded it as simply gastric. He prescribed three meals a day, restriction of meat, and rest, which gave temporary relief. Then a typical attack of angina pectoris showed the true nature of the case. In a second case a healthy farmer, aged 55 years, began to have gastric symptoms. After supper his stomach became distended with gas and he had a feeling of oppression so that he could not lie down. Eructation gave immediate relief. He was treated without effect by many practitioners for dyspepsia and then for dilatation of the stomach. Examination showed a double aortic murmur, an enlarged ascending aortic arch, and general arterio sclerosis. Rest and vaso-dilators followed by potassium iodide gave much more relief than the gastric treatment. In other cases the symptoms are intestinal, pains around and below the umbilicus coming on two or three hours after meals, and tympanites. In such cases Ortner has found after death the aorta thickened and calcified, a thick deposit of lime salts about the mouths of its branches, especially the mesenteric arteries, and the latter rigid and contracted. The small branches of the latter rigid and contracted. The small branches intestinal walls were poorly nourished and their muscular coat was weak and unequal to its work. Ortner therefore compared this condition to "intermittent claudication," which is due to arterio-sclerosis of the lower limbs. This produces ischæmia of the muscles. After walking a short distance the patient is seized with pains and limps because the blood-supply of the muscles is insufficient for exertion. Erb supposes that during the attacks there is spasm of the arteries. Similarly the abdominal attacks may be explained by arterial spasm. The interference with the blood-supply of the stomach or intestines would impair all their functions—motion, secretion, and absorption. The atony and fermentation would account for the distension and flatulence. Abdominal arterio-sclerosis may also produce other symptoms which may prove misleading. There may be pain and tenderness in the epigastrium combined with vomiting, backache, and hæmatemesis, suggesting gastric ulcer. Perutz of Munich has recently recorded a case in which he had great difficulty in excluding gastric cancer, and Dr. Akin has seen a similar case. In the diagnosis the practitioner should not be led astray by complaints of indigestion and confine his attention to the stomach, especially when nocturnal symptoms with attacks of distension, heart disturbance, and dyspnœa are prominent. Then examination of the vascular system may show a somewhat enlarged heart, an accentuated second sound, rough sounds over the aorta, episternal pulsation and hardened arteries usually with a high-tension pulse. There will also be attacks of cardiac pain radiating to the arm, tenderness over the abdominal aorta down to the navel, and perhaps urine increased in amount and slightly albuminous. Treatment for a time at least is often satisfactory. The diet should be plain and digestible. The evening meal should be limited so as to prevent flatulence. General measures, such as bathing, fresh air, suitable exercise, attention to the bowels, and relief from work, are indicated. Vaso-dilators, such as diuretin, sodium nitrite, and nitroglycerine, give good results. Diuretin in from 10 to 15 grain doses thrice daily is the most effective. Potassium or sodium iodide in from 5 to 10 grain doses for a long period is also useful.

OX GALL AS CULTURE MEDIUM FOR TYPHOID BACILLI.

As long ago as 1894 it was remarked by Fischer and Leo that Eberth's typhoid bacillus lived and multiplied within the gall-bladder. Ten years later Conradi, when examining the blood of typhoid patients for Eberth's bacillus, thought that bile would exert an anti-coagulating effect, and mixed at first 0·5 cubic centimetre of blood with 1 cubic centimetre of bile. He afterwards adopted a medium composed of bile, glycerine, and peptone. Subsequently Kayser turned his attention to bile as a culture medium for the typhoid bacillus, and after experimenting with different proportions of blood and bile came to the conclusion that the best results were obtained when 2·5 cubic centimetres of blood were sown in about 5·0 cubic centimetres of pure bile. Recent investigations made by Dr. Nicolou Bettencourt and Dr. Garcia Regalla, which are published in the *Jornal da Sociedade das Sciencias Medicas* of Lisbon, would appear to show that such a blood culture provides a more trustworthy diagnostic test in the early stage of typhoid fever than Widal's better-known procedure, which, however, is to be preferred later. The blood was taken from the veins in the bend of the elbow by means of a sterilised syringe and added to pure ox gall in small flasks, which were then placed in the incubator at a temperature of 37° C. for from 12 to 30 hours. Generally the characteristic colonies were produced in Conradi's medium in 18 hours. If the result was negative the examination was repeated for six consecutive days. The identification was confirmed by Widal's reaction and in most cases also by Kolle's quantitative agglutinative method. Of the 11 cases examined during the first week of the disease every one gave a positive result. Of the 17 examined during the second week 14 gave positive results, but only four out of the eight which were in the third week acted thus. One important point of interest to practitioners at a distance from a bacteriological laboratory was made out very clearly—that is to say, the blood-sown bile may be kept for as much as 30 hours before being placed in the incubator. Again, it appeared that the cases of slighter severity were those which gave negative results in the second and third weeks. After a long incubation, 36 hours, it was possible to distinguish typhoid from paratyphoid bacilli. While the number of cases reported in Dr. Bettencourt's paper is too small to establish the certainty of the test, the ease with which it can be employed and its apparent special suitability at the very commencement of the disease render it worthy of more extended trial. It may be remembered that more than one recent observer has called attention to the connexion between affections of the liver or gall-bladder with typhoid fever; thus, in 1904 Dr. A. Guinard[1] reported a case of large hepatic abscess occurring during the course of typhoid fever which when opened was found to contain typhoid bacilli in the pus. Subsequently Dr. B. A. Thomas[2] collected 154 cases of typhoid fever with cholecystitis, B. typhosus being found in the gall-bladder in 50 per cent. of all. Dr. Quénu[3] considers typhoid fever as a primary septicæmia, the liver being the primary agent for the elimination of the B. typhosus which is brought to it by the blood, and he thinks many jaundices are nothing less than primary infections of the bile passages by the B. typhosus. Weil's disease, too, he thinks, is probably produced in the same manner. We may refer our readers to an annotation published in THE LANCET of Oct. 10th, 1908, p. 1091, in which is recorded a brief account of the early diagnosis of enteric fever by blood culture upon Conradi's plan.

HYDROA GESTATIONIS.

ON p. 1827 we print an account of that rather rare condition known as herpes or hydroa gestationis which has been sent us for publication by Dr. Ernest Ward. The case recorded is typical, for the attacks occurred in several successive pregnancies, the eruptions appearing generally in the latter half of pregnancy and on one occasion in the puerperium. Until recently this disease was always attributed to the nervous system, but it is recognised by most dermatologists that it is probably the result of a toxæmia, such being very common at some stages of pregnancy. There are, however, probably other factors in the production of the disease. The fact that for the most part the legs are only or mainly affected points to the venous congestion which is so often present during pregnancy as assisting in causing the morbid condition, and it is not unlikely also that the instability of the vaso-motor system frequently met with in pregnancy may also be an important factor. Examinations made into the bacteriology of the fluid in the vesicles seldom show anything of importance, and it is very doubtful if microbic infection has any part in the production of the primary condition, though later secondary septic infection is very common. The onset of the affection appears to occur most frequently in the winter, from which it might be supposed that the affection was seasonal and due to cold, but it is not unlikely that the wearing of woollen, and therefore more irritating, stockings in the winter may favour the appearance of the disease in that season.

THE CORONERS' SOCIETY OF ENGLAND AND WALES.

THE annual banquet of the above society was held at the Holborn Restaurant, London, on June 17th, when Dr. W. Wynn Westcott, President of the society and coroner for North-East London, occupied the chair. Amongst the guests present were several well-known medical men. The usual loyal toasts having been proposed and honoured, Mr. G. Vere Benson proposed that of "The Imperial and Local Government," a toast which he thought imposed upon him a difficult task, but which he discussed from an appropriate point of view—namely, the relations of the office of coroner to Government administration. Those relations in the past had been satisfactory, he said, and he hoped and thought that they would continue to be so. Mr. George Radford, M.P., in replying, referred to the importance of the office of coroner. He confessed that he was not strongly qualified to speak on the subject, but he supposed that when a man became a Member of Parliament he was expected to speak on any subject. Mr. P. O. Simmonds, of the London County Council, followed in a speech which dwelt upon the exactions on the time of a councillor which the office pressed upon him. The proceedings closed with the toast of "The Officers of the Society," and during the evening an excellent, though not long, programme of music and recitals was given.

A TELEGRAM from the Governor of the Mauritius, received at the Colonial Office on June 19th, states that for the week ending June 17th there were 2 cases of plague and 1 death from the disease. As regards Hong-Kong, a telegram from the Governor, received at the Colonial Office on June 21st, states that for the week ending June 19th there were 16 cases of plague and 13 deaths from the disease.

APPLICATIONS are invited for appointment to the Chair of Surgery in the University of Edinburgh, vacant by the resignation of Professor John Chiene. Applications, with testimonials, should be lodged with the secretary to the curators, Mr. R. Herbert Johnston, at 4, Albyn-place, Edinburgh, on or before July 15th.

THE annual meeting of the Imperial Cancer Research Fund will be held at Marlborough House on Friday, July 9th, when H.R.H. the Prince of Wales, President of the Fund, will take the chair.

Mr. W. A. Mackay, M.D. Edin., of Huelva, Spain, has been awarded the White Cross of Carlos III. for distinguished surgical service rendered to the Civil Guard.

Dr. R. Deane Sweeting has been appointed to represent the University of Oxford at the forthcoming Sanitary Congress at Leeds.

MEDICAL CONGRESSES IN ST. PETERSBURG.—The Minister of the Interior has authorised the calling of an International Accoucheur-Gynæcological Congress in St Petersburg, to which end a committee has been appointed under Professor Otto. In order to acquaint foreign medical men with Russian health resorts, mineral waters, and other special curative agencies in the country, the organising committee is arranging excursions to Moscow, the Crimea, and the Caucasus. The Minister of the Interior has also granted permission to the President of the St Petersburg Ophthalmological Society, the Academician Be[illegible] to convoke the Twelfth International Ophthalmologic[illegible] gress in St. Petersburg, in July–August, 1913.

MEDICO-LEGAL EVIDENCE IN A CASE OF SUDDEN DEATH.

BY GEORGE E. WHERRY, M.C. CANTAB., F.R.C.S. ENG.

WITH the Employers' Liability Act and similar legislation there is an increasing tendency to make out that diseases are the result of accident. Among hospital patients especially there is a determined desire to put down every malady to accident. Employers of labour come themselves, or send their deputies, to the hospital to inquire about patients with motives connected with insurance awards. Thus there is more litigation in the law courts. In some cases patients attempt fraud by unfair statements; more frequently they exhibit great cunning in obtaining compensation As an example, a man in the employ of a corporation was pecking up the road with a pick when a piece of granite flew into his eye and destroyed the sight quite hopelessly. It was his only eye; the vision in the other had been lost for 20 years. When he had recovered from the shock of the accident, which had completely blinded him, I found in the old blind eye a small area of clear cornea, a probable absence of lens, and other conditions not unfavourable for operation. I therefore urged the man to let me try to give him a little sight, especially as there was nothing to lose and he might gain something. Nothing would induce him to permit any operation, and he left the hospital. But some months after this he came to me, he having obtained the full compensation awarded for total blindness. He then wished to be operated upon; as a result he gained fair guiding sight and a very different outlook on life. The foregoing remarks are merely a preamble in justification for offering to print a short history of a recent medico-legal experience, only withholding or substituting names and avoiding unnecessary details in my narrative.

A man named Luke left his home in the Fens at 9 o'clock in the morning in his usual good health to buy potatoes, and he bargained and chatted until 4.30 P.M., when he left the "Red Ruin" public-house and got into his cart, which was waiting outside, to drive home again. He waved his hat and was very cheerful, and drove in such a manner as to bring two neighbours off the fields; these stopping the horse rather suddenly caused Luke to fall off the shafts on which he had been lounging. He remarked to one of the neighbours, "Oh, the drink, Mr. Quarto." By the fall he got an abrasion of the left cheek whic [illegible] fell, or partly f [illegible] n ing himself ag [illegible] o clothes talked [illegible] recovered, so that and chatted and seemed to have entirely recovered, so that at about 5 50 the constable left him in charge of his horse and cart. The horse was known to be shy of motors and engines At about 6 o'clock, some ten minutes after the departure of the constable, Luke was aware of a road-engine approaching in front of him; he held up his hand and walked by his horse, but the engine-driver refused to stop, until a postman coming up the engine at last did stop, and the postman passed by. Luke tried to pass also, but his horse became more and more restive, pulled his master along, and in the struggle threw him down violently and dragged the cart over him. He died in a minute [illegible] The constable who had left him at 5 50 saw the [illegible] at 6 10.

By the coroner's order an examination of the [illegible] made by the nearest medical practitioner [illegible] after the death. There was an abrasion [illegible] prominence and no other marks on the [illegible] The brain contained a sub-dural clot of the [illegible] the right cerebral hemisphere; [illegible] vessels. At the inquest the [illegible] that [illegible] blood [illegible] the n [illegible] accou [illegible] that in any case he [illegible] home.

More than a year [illegible] compensation for the [illegible] tried before a judge without a jury. Besides the medical evidence already quoted a physician attending as an expert witness came down from London. He agreed with the opinion that the bleeding which killed Luke came on soon after 4.30 outside the "Red Ruin," and accounted for the staggering gait and other vagaries described, and that he would have died in any case when he got home. Accounts were related of men supposed to be drunk being put into prison cells and found dead in the morning from an intracranial bleeding. Luke was said to have had a period of recovery, and then the excitement and struggle with the horse proved fatal or accelerated the inevitable end. The widow's advisers asked me to give evidence, and I read the depositions, and was in court all the second day of the trial to hear the witnesses on that day. When the evidence of the two medical men had been taken there was an attempt, on some legal point, to prevent my evidence being taken; but the judge overruled this, allowing at the same time the other medical men to have the last words in a recall for a second examination. The salient points of my rebutting evidence the judge appeared to take down in longhand. I quote from a newspaper this paragraph.

> Mr. Wherry stated that in view of what he had heard he considered that Luke died from external violence and without that violence he might be alive now. The suddenness of the end was what he chiefly relied upon in this statement. Cases of hæmorrhage without external violence did not die in a minute or two, except in very rare cases in which the vital centres were attacked. A bleeding the size of a pigeon's egg, laterally placed and formed without external violence, would have required at least *an hour* to cause death. Sir William Gowers would give at least *two hours*. In this case [illegible] sudden, and he contended that this was [illegible] external violence. It was very easy to acc[illegible] dition of the man by assuming that he was [illegible] had been dazed by a fall from which he afterwards recovered. He did not think it fair to say technically that th[illegible] He believed the man died of concussion [illegible] once the vital centres, both respiratory an[illegible] that without external violence the man wo[illegible]

In cross-examination I was asked to listen to a sentence from a standard book on medical jurisprudence. How a man with cerebral hæmorrhage might appear to be drunk and then be clapped into a prison cell where "he would suddenly grow worse and die." "Do you agree with this?" "*The growing worse is sudden, but the death is not sudden.*" "Then do you say the book is wrong?" "*I am allowed to make comments and interpretations.*" "Was Luke drunk when he came out of the 'Red Ruin'?" "*He was market-merry.*" "That may be a pretty expression; but was he drunk?" "*He was happy, he waved his cap; you will allow that there are stages.*" "But was he drunk?" "*You wish me to answer yes or no?*" "Certainly." "*Then you wish to dictate my answer. He was not drunk when the constable left him.*"

It was necessary for me to show that the fall which caused the abrasion on the left cheek did not by contrecoup cause the clot on the right side of the brain. This would have meant a great commotion and a period of unconsciousness, not a period of merriment. Luke also probably became rather over-cautious as he recovered from his first excitement. About a month later the judge gave judgment for the plaintiff for the full amount claimed, with costs.

Apart from the question of drunkenness, which in these cases must be often a matter of opinion, there is the very serious question of the antecedent bleedings and clot formation in cases of death from violence. Here is a case of a man, coming out of a public-house, who is thought to be drunk by his friends, and thinks himself so. He is drunk as to his legs if not as to his head. He recovers, and is considered to be sober by an experienced constable. Then he is killed suddenly by a violent fall, and the medical evidence is to the effect that intracranial hæmorrhage began an hour and a half before the suddenly fatal end. If in giving this narrative I have taken too much my own point of view, this need not affect the real interest of the case. One has only to suppose it to be a trial for murder to realise the importance of this sort of experience to our profession.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* The title of Professor has been granted to Dr. Arthur Alexander, *privat-docent* of Laryngology, and to Dr. Max Levy-Dorn who has charge of the Röntgen Institute in the Virchow Hospital.—*Breslau:* Dr. Hans Vogt, Assistant Physician in the University Clinic for Children, has been recognised as *privat-docent* of Pædiatry.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

On the Cost of Running a Small Single Cylinder Two-seated Car.

Mr. F. H. Preston of Plumstead bought in September of last year a 6-h.p. Rover car, an automobile which I described in THE LANCET of August 22nd, 1908. This car was used daily, and in six months he covered 1552 miles. He has very kindly given me the following particulars as to the cost of running for that period, and as they seem about the average that a medical man who buys a good little two-seater car, such as the Rover, Darracq, small Star, little Renault, &c., may expect, I am publishing them; they should be some sort of guide to prospective medical motorists:—

	£	*s.*	*d.*
* Petrol (77 gallons)	4	1	1
Lubricating oil (10 gallons)	1	7	0
Kerosine (used for cleaning)	0	1	6
Cleaning odds and ends, selvyt, spoke brush, pipe-clay, brasso, chamois leather, &c.	0	4	6
Waste, oil can, funnel	0	7	4
Repairs (glass to replace broken one in mileage recorder), repairs to radiator, clutch, and accumulator...	0	11	6
Pair non-skid covers	8	17	0
Annual licence for car (under the new Budget this would only be £1 1s., but to compensate the petrol for six months would be 25 per cent. dearer)	2	2	0
Licence for male servant (for the year)...	0	15	0
Water-rate (year's tax)	1	0	0
Total	£19	6	11

Mr. Preston tells me that the car was out every day, and excluding a puncture on one occasion he has not had any delays. The tyres were bought as spares and should consequently be charged to a special annual account and not to the six months. From personal experience I find that with ordinary running and luck two covers a year and one or two tubes are ample; with extra heavy covers on the back wheels they should run for a year, and then if re-treaded, do for another year on the front wheels. Non-skids, however, do not last as well: nine months' constant wear is about the life of a studded cover on a back wheel. The taxes apply to a year's running and not to the six months. The garage was in a stable on the premises and is not charged. The motor attendant, who does other duties, is likewise not charged for. Probably a lad at 10*s.* a week could do the work. The accumul[illegible] it home off the main, a switch with [illegible] Thus charging half cost of new tyres, half water-rate and licences, and 6*s.* for charging of accumulators, the cost for six months' running [illegible] wage of motor-cleaner amounts to £13 5[illegible] a mile; and this is what a light car driven by the owner should come to, or say with a fair allowance for repairs £30 to £40 a year, and such a car should run for five years. I myself still use a little 6-h.p. Wolseley, which is six years old and has not cost more than £35 a year to run, including tyres, spare parts, petrol, oils, &c., but excluding the cleaner. I certainly consider my car to be now as good as when I bought it and expect to use it for many a year to come.

Head Lights Brackets.

I have had some queries sent me regarding my notes, published in THE LANCET of May 8th, as to the best bracket for a single head light. I believe the simplest fitting is to bolt under each front spring a curved piece of wrought iron so shaped that the two ends come in front of the radiator and are the correct distance from one another, so that the bracket holes on either side of the lamp can respectively drop over these ends. Any blacksmith will bump out such pieces for a couple of shillings, and the ends which fix to the springs can be so shaped that they can be fixed and held under the bolts which attach the radiators to the springs or front frame of the car, as the case may be. If they are made so that the lamp is just above the radiator they can be given a slight tilt forward so that the beam of light from the lamp illuminates the near ground as well as the road ahead.

On the Choice of a Head Light.

Messrs. Joseph Lucas, Limited, have written in reference a previous article of mine on this subject that their latest

st. It certainly threw out a broad beam of light of great tensity straight ahead, which evenly ill

the car, but I still felt, in fact noted,

r in another one that the light was somewhat dazzling to yone approaching. I, however, fail to see how any lamp n absolutely avoid this, and in this particular lamp it is duced to a minimum. I gave the lamp a fairly good test, I came on a very dark night all the way from Bexhill to oolwich; the first part of the journey I purposely took *via* rrow cross-country lanes through Ninfield, and by the cellent light that the lamp gave I was able to go as ickly as in daytime. I can certainly recommend these head ghts for all who have to drive a motor at night-time in unlit untry winding roads.

Some Points in the care of Acetylene Lamps.

The great thing with all acetylene lamps is to keep every rt clean; it pays, and at the end of a run turn off the ater first, then the gas, and do not let the light burn out. you neglect this, then you have only yourself to blame if lf an hour is wasted fiddling with a wrench to remove the rner, and then with a needle or bit of wire to clear a ocked jet. As for carbide, any ordinary dustless kind swers; that of the same size as is used for cycle lamps the best—that is, bits not quite as large as monkey-nuts.

Extra Electric Lamps.

Those who prefer not to rely on one system of illumination ill like the simple electrical connexions made by Messrs. ucas. They screw into the back light and are well out of e way. The petroleum burner remains in position while e electric lamp is used, and it is only needful when rning oil to remove the electric bulb.

Some Points in the Diagnosis of Automobile Torts.

The process of correct solution of motor-car maladies is ry like the method we were taught to adopt in our student ys when essaying to solve the obscure medical and surgical ddles which we then encountered. Firstly, a list of the ssible diseases is made, and these severally are then struck t by proving that they cannot exist, until finally but one mains, and that as a rule is the true one, chiefly because ery other possible source of morbidity has been eliminated. nother point of similarity is that, as in one's medical work, in automobile affairs, the most simple is often the real planation. The young energetic man fresh from the test seat of learning is rather keen on holding forth on a se of erythema, and speaks of the cocci of Luzzato, while e older general practitioner probably correctly diagnoses "measles." It is just the same in automobile matters. ecently I was talking "petrol" with a medical friend; he

four-cylinder car

nd high-tension

used to leap up

ow made it jump and groan and call for the low gear. My llow automobilist was worried; the ignition, he said, was rrect, the plugs clean, with points the correct distance part, and the car was vile when the two methods of exploding the mixture were acting together, as well as when ey were acting separately. The petrol had paid duty and as good, and the carburettor jet was not blocked; even e petrol tap was not turned off, neither were the brakes n, nor did they foul the drums. The questions submitted were: Does the engine need dismantling? Has crank-bearing fired? Is there a broken piston-ring? as a ball-bearing in the transmission-gear seized? On examination it was found that the engine started easily and the arburettor, when the needle valve was agitated, flooded, o there was no doubt that the petrol-supply was correct, nd as the automatic air inlet worked it was positive that he mixture was suitable. The brake drums were cool after run; so they could not be holding the car back, the gearox bearings were like ice cold, so that loss of power due to riction in

The simplest xplanation.

he engine was tarted with both ignitions on, and each plug, with the engine running, was shorted by means of the metal end of a screw-driver; it was then discovered that the high-tension plug of No. 3 cylinder did not spark, also when the magneto plug of that cylinder was taken out and shorted on the frame that that plug did not spark at the points. The problem was thus very simple: the engine lost power because, even with double ignition, one cylinder was missing fire, one plug had become oily and so was shorting internally, the other did not fire because the trembler contact blade

the commutator had worked loose and the platinum

ere were too far apart. After an adjustment that took but a few minutes the car regained all its lost power. I only make mention of this case as it shows that motor worries are often due to very trivial causes, and that these, with a little thoroughness in examination, can, as a rule, be quickly detected, and then, of course, equally rapidly cured.

The 14–16 H.-P. Darracq.

This car belongs to that type of automobile which is now so popular; it is one of the light fours, light on tyres, and also, because of its moderate but ample horse-power, light on its owner's pocket in the matter of tax and petrol. Personally, I believe that the popular demand that even small cars should have four-cylinder engines is wrong, especially for members of the profession who drive themselves. With a single cylinder the owner, in order to obtain a decent speed, keeps the ignition and compression at concert pitch, and soon learns how to manipulate his throttle and ignition levers so as to get the best result out of his engine. With a four cylinder there is a reserve of power, consequently the owner may not always keep his car at concert pitch. Still, of course, four cylinders are more silent and more powerful anyway when kept tuned up. But to return to the car under consideration. It has a wheel base of 8 feet 6 inches and can well take a roomy side entrance body or, for those who like to be driven can be made into a landaulet. The engine is of the *moteur bloc* type, the four cylinders and valve chambers being all cast in one piece; the bore is 85 millimetres and the stroke 100 millimetres. The valves

erated by a single cam shaft, and

on this shaft is brought

used in conjunction with

ntly had a good proof of the real need of having two separate systems of ignition. I was out in my car, driving on the magneto, when she suddenly stopped; the accumulator method of exploding the mixture was switched on, and without any delay I was able to proceed home. Inspection then showed that the magneto could not have been repaired on the road; the carbon brush was clean, the platinum points were the correct distance apart, and they made and broke contact correctly. The fault was with the slip ring which had burnt out, and the armature also required recovering, defects which could not possibly have been seen to on the road. So if any medical man invests in these truly excellent little cars I strongly

counsel a double ig

experience and some

car, as my partner o

over a year, and during that time his repair bill merely amounted to 9*d*. The older type had, however, serious constructional defects: the magneto was on the valve side of the engine, and in order to get the valves out, so as to grind them in, the magneto had first to be removed; the valve lifters, too, had solid ends. The new 1909 type, which I inspected in course of construction at the well-equipped Darracq works at Suresnes, is greatly improved; the magneto is now on the other side of the engine and is driven by the shaft that drives the water circulating pump. It is held in position by a screw clamp which abuts against a lug specially cast for the purpose on the cylinder; thus on the release of one accessible nut the magneto can be removed. Those who have had to first drop the shield and then crawl, to the damage of their attire, under the car frame to undo two nearly inaccessible nuts will, I am convinced, appreciate this undoubted great improvement. The valve lifters, too, have rollers where they come in contact with the cams and are made of steel working in cast-iron guides. The carburettor is of the float-feed and spray type, and an automatic air intake ensures

point now

great economy

ure that I

that there is a

at I should

should like to see altered about this

like to be able to remove the jet without taking down the carburettor, and I should also welcome a carburettor that could be dismantled without having first to slacken the inlet and exhaust pipes. Still, as a fine gauze washer is interposed where the petrol pipe enters the float chamber, there is little likelihood of having to do this operation. I have driven one of their higher powered cars, and only once was I held up by a blocked jet, and then that was my own fault, as instead of cleaning the gauze strainer when it was blocked by dirt I pushed a skewer through it, and thus permitted foreign matter to get to the jet. Lubrication is well provided for, and in lieu of the not altogether satisfactory pressure feed lubricator, one worked by a pump, operated by a rod from a little crank on the end of the cam shaft, is fitted. The clutch is of the leather-faced cone type, and the gear box is fitted with three forward speeds and a reverse speed. The propeller shaft transmitting the power from the gear box to the live axle has two flexible couplings, and a torque stay, anchored to the frame by a spring, takes up the thrust. A straight through quadrant of the Panhard type is employed for the gear changing. The throttle is worked by either a lever on the steering column or by a small foot pedal; the latter is probably the best to use, as it leaves the hands free for gear changing and performing on the hooter. The brakes are of the internal expanding pattern, and means for adjustment and taking up of wear are provided. As to the running of the car there is little to be said except that the engine has a good reserve of power and that nearly all hills can be climbed on the second gear, and that the liveliness of the car and the way it can be handled are delightful.

Messrs. Darracq also manufacture a [illegible] seater, as well as an 8-10 h.p. and a 10-[illegible]; the latter is also turned out as a four-[illegible] a phaeton or detachable tonneau body. I have had many opportunities of testing these models, opportunities, too, when the cars have been driven and looked after by medical men or their chauffeur grooms, which of course is a better means of judging, than when the car is sent from the makers with an expert driver, and I must say that I have invariably found them trustworthy. In addition, the springing is luxurious, an especially important point for a medical man, who has often to spend from seven to eight hours a day in his car.

THE INSTITUTE OF PHYSIOLOGY AT UNIVERSITY COLLEGE, LONDON.

THE new Institute of Physiology at University College, London, was formally opened on Friday, June 18th, by the Right Hon. R. B. Haldane, M.P., Secretary of State for War, and the occasion was made into an interesting academic festival. The Vice-Chancellor of the University of London, Professor M. J. M. HILL, presided, and throughout the inaugural ceremony care was taken that those present should realise to the full that the new building has an importance other than that of the establishment of a first-class physiological laboratory in one of the most important teaching centres of London. Mr. HALDANE, who in the present Government may be considered the "Minister for Universities," regarded its successful completion as a sign that England was fully alive to the importance of promoting higher education, and he quoted as analogous examples of this righteous spirit the recently founded universities of Birmingham, Liverpool, Manchester, Leeds, Sheffield, and Bristol, and the new universities of Ireland. With such examples before him, he found it quite impossible to accept the gloomy views so often advanced as to the backwardness of Great Britain in the more advanced departments of knowledge. It was a healthy sign, he said, that the Government and the Treasury were waking up to the necessity of meeting the requirements of higher learning. He regarded the Institute of Physiology of University College, London, as an object lesson to the country.

In an introductory address, Lord REAY, President of University Coll[illegible]. London, struck an imperial note, pointing out that [illegible]Dorn w[illegible]shment of the Institute of Physiology was [illegible]archow Hospit[illegible]in which University College had done its[illegible]ysician in the Un[illegible] the idea that it was the mission of [illegible]cognised as *privat-*[illegible]highest centre of learning within the Empire. He expressed the hope that the generosity of the friends of the College would make it possible shortly to complete the full scheme of an institute of preliminary medical studies—anatomy, pharmacology, and physiology.

Sir ARCHIBALD GEIKIE, President of the Royal Society, and Dr. H. A. MIERS, Principal of the University of London, moved and seconded a vote of thanks to Mr. Haldane, and the latter referred especially to the rapid development of corporate life within the university.

Professor E. H. STARLING, the only other speaker on the list, expressed in his own name and that of his colleagues the gratitude they felt to Mr. Haldane, to the eminent foreign biologists, and to others present for the sympathy they had shown. Mr. Haldane, he contended, was specially fitted to perform their opening ceremony because of the interest he took in the progress of University education, and because in his army scheme the lesson he had tried to instil was the ideal of service for the good of the community, an ideal essential in the work of the laboratory. The workers who were forming a brotherhood among the nations were, he contended, leading the way towards the brotherhood of the nations. He imagined that Mr. Haldane, through the lines of his battalions, could see a time when civilised men would all be common workers in the service of humanity. In conclusion, he claimed that the presence of the Presidents of the Royal Colleges of Physicians of London and Surgeons of England constituted the acceptance by the medical profession of the principle that all medical knowledge must be based on experiment.

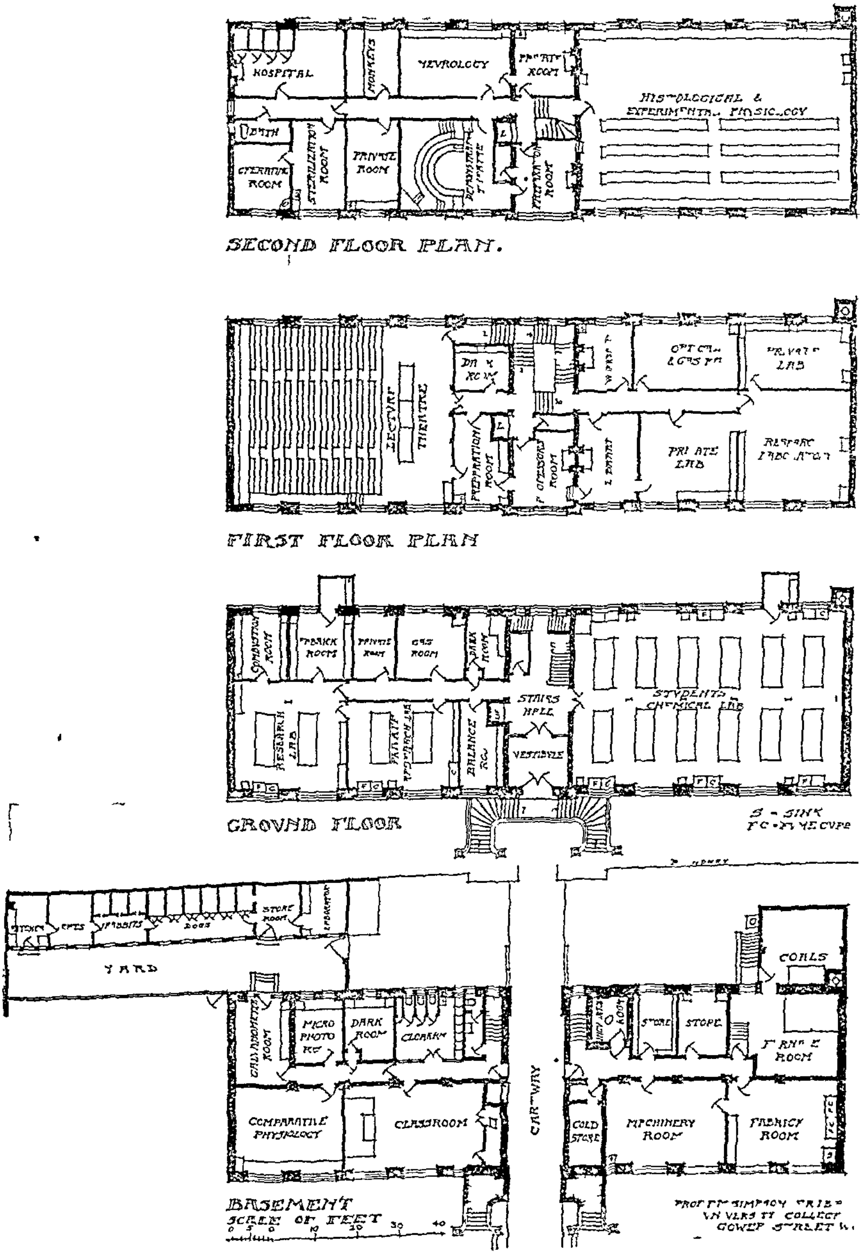
In his reply, Mr. HALDANE compared the present knowledge of science as a link between civilised nations to the knowledge of Latin possessed by scholars during the Middle Ages. Mr. Haldane then inspected the University of London Officers' Training Corps, which paraded, some 250 strong, in the quadrangle.

The Institute of Physiology remained open until 7 o'clock, and was inspected by those who had attended the ceremony of inauguration. Substantially, the building consists of four floors, basement, ground, first and second floors. (Fig. 1.) Each of these, except the basement, contains one large room about a third of the area of the building, devoted on the ground floor to physiological chemistry, on the first floor to a large lecture theatre, and on the top floor to a laboratory of histology and experimental physiology. These three rooms, a small demonstration theatre, well equipped with apparatus, recording and otherwise, and so constructed that 40 students can obtain a full view of any experiment, and a classroom for tutorial and other purposes in the basement, constitute the portion of the building devoted to the work of the students. The rest of the building is allocated to research.

The most notable feature of the teaching portion of the laboratory is the magnificent lighting that has been obtained, the maximum space structurally possible having been devoted to windows. Elaborate precautions have also been taken for efficient ventilation, a fan having been installed capable of providing a current of 12,000 cubic feet a minute through any one of the three large rooms. The fan normally removes vitiated air from the different rooms in the building, but by means of shutters in the main extract flues can be concentrated exclusively on any one of the more important rooms. Among other good features are the following. The six double fume cupboards in the chemistry laboratory are extensive and well lighted. On the west side of the laboratory is a balcony roofed in with glass but open at the back and sides, and thus suitable for manipulations involving the production of objectionable fumes. The lecture theatre is furnished with an ordinary lantern and the large epidiascope of Leitz. The windows are provided with light-tight blinds that can be raised or lowered in 20 seconds by means of electric motors, set into action by switches on the lecturer's table. The histology and experimental physiology laboratory is lighted by large windows at both sides and by a continuous skylight. Three of the histology benches are provided with continuous shafting, and five tables are also specially fitted for the purpose of experimental physiology, and in this laboratory, as throughout the building, all gas- and water-pipes are easily accessible and differentially coloured. Annexed to the laboratory is a small preparation room.

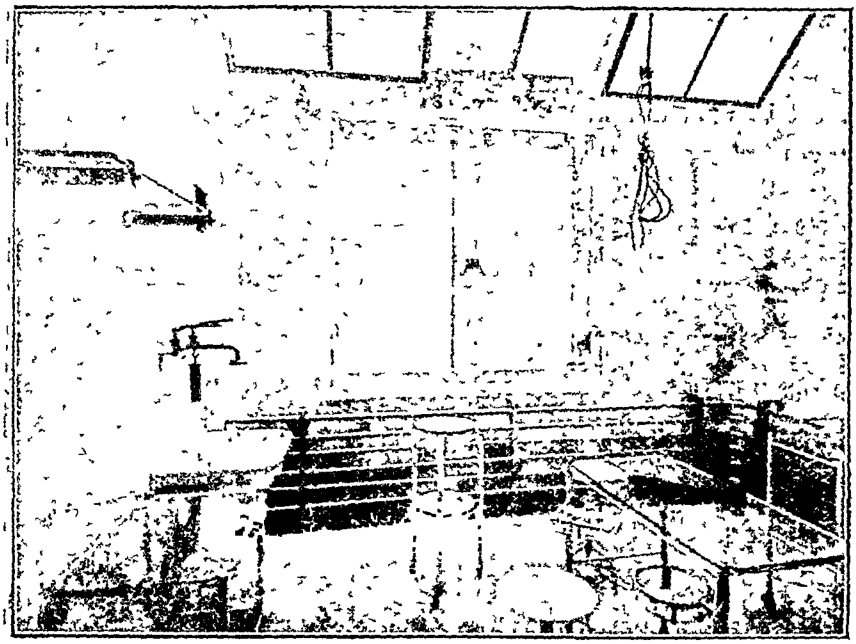
In the large portion of the building devoted to research there are, apart from the thoroughness with which such general

FIG 1



Plans of the new Physiology Institute University College London

FIG. 2.



Aseptic Department. Operating Room.

principles as that of specialisation are accepted, two outstanding features—the aseptic department and the elaborate provision made for the health and comfort of the animals. The aseptic department (Fig. 2) is on the second floor and consists of sterilisation-room, operating-room, bath-room, and animal hospital. In the operating-room similar precautions are taken to those taken in the hospitals. There are double windows to enable the room to be kept at a high temperature, specially constructed radiators to prevent the accumulation of dust, a supply of hot and cold water, and so forth. The hospital is provided with four glazed-brick kennels for dogs, and has ample space for cages for other animals. Outside the building is an outhouse containing half a dozen rooms, with kennels, cages, &c., for keeping animals, for preparing their food, and so forth. The second floor also contains a room for histological research, a room for keeping monkeys in, a laboratory for the study of neurology, and a small room for the use of the teachers in charge of histology or experimental physiology.

Apart from the lecture theatre and its preparation-room the first floor consists of the Thomas Webb research laboratory, and contains six rooms, a departmental library with accommodation for about 4000 volumes, the professor's private laboratory (Fig. 3), fitted with shafting and electric power and a chemical bench, a general research laboratory somewhat similarly fitted, but also containing two kymographs, a room for accurate physical observations, occupied by Dr. Bayliss, a large room for optical work or for investigations requiring the use of mercury gas pumps, and a small workshop. A small mezzanine floor contains laboratories, cloak-rooms, and so forth, and a committee-room. The ground floor is reserved for chemistry and contains a balance-room, a well-equipped private laboratory for the assistant professor in charge of physiological chemistry, a combustion-room, a distillation-room with an annexe roofed with glass and similar to that described above in connexion with the students' laboratory, a private office, a gas- and optical-room, and a room fitted with double doors and able to be darkened suitably for polarisation work. A large portion of the ground floor is devoted to stoves, heating apparatus, and similar purposes, but it also contains the following useful rooms: a refrigerating chamber with a storage space of 6 feet 6 inches by 10 feet by 7 feet 6 inches; a machinery room, with centrifuges, grinding mills, &c.; a *fabrik-raum* for working up materials on a large scale; an incubator chamber; a room for comparative physiology; a galvanometer room, at present used for the servants of the institute; and two dark rooms for photomicrography, &c. One of these is fitted with a masonry pillar with slate top to provide a support, free as far as possible from any vibration. It should be added that in the upper three floors of the building the rooms are divided up by Mack partitions so that they can be entirely rearranged on any floor at small expense.

The following statistical details may prove of interest. Dimensions of institute, 44 feet by 144 feet; cost of building and equipment, £20,500; dimensions of theatre, 50 feet by 14 feet by 19 feet, accommodates 200 students; dimensions of chemical laboratory, 62 feet by 40 feet: dimensions of histology and experimental physiology laboratory, 63 feet by 42 feet; dimensions of animals' sheds, 12 feet by 76 feet. The power used throughout the building is electricity. The heating is by hot water.

Academic dress was worn at the opening ceremony and a distinguished company included the Presidents of the Royal Colleges of Physicians of London and Surgeons of England, Professor M. J. M. Hill, Lord Reay, Sir Archibald Geikie, Sir William S. Church, Dr. H. A. Miers, Dr. T. Gregory Foster, Sir Felix Schuster, Professor Millar Thomson, Professor Sidney H. C. Martin, Professor D. S.

THE MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN.

ON June 21st a conference was held at the Institute of Hygiene on the subject of the Medical Inspection and Treatment of School Children. The conference room was well

The PRESIDENT explained that the meeting had been called in order that some definite information on the many important questions involved in the subject of medical inspection might be obtained and forwarded to the proper
Two points must not be lost sight of—the da
minimising parental responsibility and the recognition of the interests of the medical practitioner in relation to the treatment of State-educated children.

The first motion, proposed by Dr. J. C. THRESH (medical officer of health of Essex) called upon the Board of Education to issue definite instructions securing uniformity in the statistics relating to medical inspection. Dr. Thresh had prepared the following statement:—

Statistics based on Reports received from 20 Counties and Towns in England (Children Examined, over 40,000).

Reported to be suffering from—	Percentage.		
	Lowest.	*Highest*	*Apparent average.*
Tuberculous disease	0 015	4 3	0 8
Bodily deformity	0·04	6·0	2 4
Defective nutrition	0 3	19·0	8·0
Uncleanly head and body ...	1·0	60 0	18·0
Decayed teeth	0 7	25 0	8·0
Enlarged tonsils	2 0	23 0	13·0
Adenoids	1·5	21 0	6·0
External ear disease	0 8	3 5	1 8
Eye disease	0 4	8 7	3·0
Defective vision	4·1	39 0	13·0
Mentally defective .. .	0 3	4 2	1 3
Heart disease	0 4	5 0	1 5
Lung affection	0 1	2 4	1 4
Skin diseases	0 9	2 1	1 9

The total result of the figures was that 74·9 per cent of the children examined required attention, though some allow-
Dr. Thresh remarked
be expected to deal

Dr. J. F. BUTLER H. HOGAN seconded the motion, which was carried unanimously.

Mr. J. HERBERT PARSONS proposed the second motion:

> thorities should be responsible for seeing
> cal inspection of school
> e methods adopted due
> practitioners doing the
> as possible, recover the
> e children attended.

Mr. Parsons expressed himself in favour of the establishment of school clinics for ophthalmic cases. It could be done quite satisfactorily without very large expense The hospitals would not suffer if the school oculists, in the case of London, did the work which their titles suggested, instead of performing duties which teachers or nurses could easily be instructed to do. But why treat all classes of disease in school clinics? To treat adenoids the clinic would have to be a hospital. Different methods should be adopted to meet different circumstances.

Mr. H. S. BARWELL thought that it would be a good thing if the hospitals would fall in with the wish of the London County Council to utilise existing institutions, provided it was certified that patients were unable to pay, and that the almoner's department should watch the cases. Payment should not be in the form of subscriptions or donations or it would open the door to the suggestion that the Council should be entitled to appoint a certain number of governors. The Council should pay by means of a capitation grant of an elastic kind. He feared that, if the hospitals said "No" and compelled the Council to face the question of starting clinics, the whole matter would lapse, and especially that dental treatment, which had not yet been decided upon, would never be undertaken.

Dr. DAVIDSON described the treatment of school children by public authorities as another attempt to encroach on the rights of the general practitioner.

In reply to Dr. LILIAN CHESNEY, who asked what was to be done in country districts where hospitals were not available,

Dr. STEPHENSON described the practice in Somerset in dealing only with ophthalmic cases The school population
yearly inflow of new children was 7000.
quired to have their refraction tested.
this 700 needed to be seen more than once a year; by doubling the figure they got 1400. Perhaps 400 were attended by other means than by the county council. They appointed an ophthalmic surgeon for £100 for ten weeks' service, and he could see 20 children per day per school week of five days, or 1000 children in ten weeks. Spectacles were bought under a large contract for 2s 6d. a pair and supplied free to the comparatively few parents who were unable to pay for them.

The motion was then carried with three dissentients

further proposition to the effect
avail themselves, in the
ns for the treatment of children whose parents were unable to pay. This would be an excellent thing, he said, for large and small hospitals.

Dr. BARLOW seconded, on the ground that general practitioners would lose nothing if this principle were adopted.

The motion was carried.

A vote of thanks to the President terminated the proceedings.

BRITISH MEDICAL BENEVOLENT FUND.

AT the June meeting of the committee 15 cases were considered and grants amounting to £129 made to 12 of the applicants, two cases being passed over and one postponed for further inquiry. Dr. F. G. Crookshank was appointed honorary local secretary at Barnes and Dr. C. E Solomon an additional local secretary at Liverpool. Appended is an abstract of the cases relieved:—

M.R C.S., L.R C P., aged 33 years. Has had a small country practice but for the last eight months has been incapacitated by general paralysis of the insane and is now confined in an asylum. Small savings have been quite exhausted by providing a locum tenens and by unavoidable expenses of the illness, and so far it has not been possible to sell the practice Two children, the younger only a few

£14 a year from the Admiralty and receives a little help from Lloyd's Patriotic Fund. Relieved 12 times, £70. Voted £5.

Daughter, aged 62 years, of late M.R.C.S., L.S.A. No income, and being mentally deficient is dependent on a relation who can only help with difficulty. Relieved three times, £36. Voted £12.

Widow, aged 62 years, of L.R.C.P., L.R.C.S. Edin. Since being left a widow, nearly 15 years ago, has supported herself by taking lodgers but finds the necessary work increasingly difficult. Two children, one just self-supporting, the other still at school. Relieved twice, £24. Voted £12.

Widow, aged 31 years, of L.S.A. No income; endeavours to maintain herself by nursing, but has been incapacitated during the last three months by acute rheumatism, and is told that a rest is absolutely essential before taking further cases. Three children, ten to three. Relieved twice, £15. Voted £10.

Widow, aged 53 years, of L.R.C.P., L.R.C.S., Ireland. Since husband's death has endeavoured to support herself by maternity nursing, but is now nearly blind. Relieved 15 times, £137. No children. Voted £12.

Widow, aged 59 years, of M.D. St. Andrews. No income. Slight occasional help from children. Lets lodgings, but has been obliged to part with some of her furniture to make both ends meet. Relieved five times, £60. Voted £12.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

A COMPLIMENTARY DINNER TO DR. J. F. W. TATHAM.

THE retirement of Dr. J. F. W. Tatham from the post of Superintendent of Statistics in the General Registry Office was made an opportunity for entertaining him to a complimentary dinner at the Grand Hotel on June 17th.

The chair was occupied by Sir Shirley F. Murphy, who was supported by Dr. F. J. Allan, Dr. Bushell Anningson, Dr. G. Paddock Bate, Dr. Sidney Barwise, Dr. W. A. Bond, Dr. G. S. Buchanan, Dr. H. Timbrell Bulstrode, Mr. Brudenell Carter, Dr. A. K. Chalmers, Dr. S. Monckton Copeman, F.R.S., Dr. Sidney Coupland (Lord Chancellor's Visitor in Lunacy), Mr. R. Musgrave Craven, Mr. George H. Day, Dr. T. Hugh Dickson, Sir William Dunbar (the Registrar-General), Lieutenant-Colonel R. H. Firth, R.A.M.C., Dr. Wilfred W. E. Fletcher, Dr. F. E. Fremantle, Mr. Kenneth Goadby, Dr. James Kerr, Mr. George King, Mr. R. O. K. Lempfert (representing Dr. W. N. Shaw, F.R.S.), Dr. R. Bruce Low, Lieutenant-Colonel W. Grant Macpherson, C.M.G., R.A.M.C., Dr. J. Middleton Martin, Dr. J. C. McVail, Mr. G. Millson, Dr. A. A. Mussen (representing Dr. E. W. Hope), Dr. Arthur Newsholme (principal medical officer to the Local Government Board), Dr. G. Newman, Dr. James Niven, Colonel J. Lane Notter, Dr. H. Franklin Parsons, Dr. J. F. Payne, Dr. George Reid, Professor W. J. Simpson, Dr. S. Squire Sprigge, Dr. T. H. C. Stevenson, Dr. R. Deane Sweeting, Dr. J. F. J. Sykes, Mr. A. C. Waters, Dr. B. A. Whitelegge, C.B. (H.M. Chief Inspector of Factories), Dr. Dawson Williams, Dr. C. W. F. Young, and Mr. G. Udney Yule. Dr. W. H. Hamer and Mr. Herbert Jones acted as secretaries.

After the loyal toasts had been honoured Sir SHIRLEY MURPHY proposed the health of Dr. Tatham, and in referring to the long connexion of the latter with all that concerns public health, he said: "We might with appropriateness speak of his 16 years' service at Somerset House as the crowning work of his life. Some people would say that they had never heard of Dr. Tatham, but we who are engaged in public health work know more than any others how greatly this country is indebted to him and are therefore delighted to gather together to do him honour. Dr. Farr, one of his predecessors, realised what could be made of the classification of diseases, and his system was so able that it only wanted modification. Dr. Tatham, in modifying it, has brought it into line with modern scientific ideas." Sir Shirley Murphy continued by saying that he would not be exaggerating if he alluded to the joint work of Dr. Tatham and of the Registrar-General as being one of the most active causes that could be found in diminishing the death-rate in this country. The tables that had been published in the reports of the Registrar-General were lessons of the first importance, and those relating to infantile mortality had thrown much light upon the causes of death among young children. When the system of death registration was first proposed it was not intended that the cause of death should be included in the information asked for, and it was only during the passage of the Bill through the House of Lords that this requirement was inserted. Although medical certification of death became compulsory in 1874, Dr. Farr some time previously had approached the Royal Colleges and the Society of Apothecaries with a view to inducing medical men to certify the cause of death voluntarily, so that it was due to the medical profession to say that in 1874 Parliament was only continuing work which had been engaged in by our profession for some time. One of the earliest subjects which attracted the attention of the Society of Medical Officers of Health was the necessity of knowing not only the number of cases of death, but of illnesses also, and Dr. Tatham, while medical officer of health of Manchester, took up the question of notified disease and made arrangements with his colleagues to send him records of disease in their districts, he himself distributing [illegible] he reporters. When Dr. Tatham [illegible] Local Government Board took over and extended this most useful work. During the time that Dr. Tatham had been at Somerset House great changes had taken pla[illegible] not too much to say tha[illegible] best medical knowledge [illegible] After referring to the admirable work which Dr. Tatham had done as chairman of the Statistical Committee of the Cancer Research Fund and as a member of the Inter-Departmental Committee on Physical Deterioration, Sir Shirley Murphy concluded by recalling the fact that their guest's earlier life had been spent as a public health administrator, and pointed out the advantages to the State of being able to obtain recruits for responsible offices from among those who had already shown themselves to be men of parts. In conclusion, Sir Shirley Murphy said that Dr. Tatham had always seemed to be the servant of the public health world, and so ready was he to render help to all those who asked for it that he had made them feel that they had a right to his services and to his assistance.

Sir WILLIAM DUNBAR said that he was glad to be present that evening, not only to show his appreciation of the work of Dr. Tatham, but also to have an opportunity of thanking medical practitioners for the way they had helped his bureau. Sir Shirley Murphy had spoken of the remarkable services of Dr. Tatham, and he was in the fortunate position of being able to confirm the chairman's words as few others could. The seven years he had spent at Somerset House had been made much happier and much pleasanter because it had been his good fortune to be associated with such an able colleague as Dr. Tatham. Indeed, not being himself a statistician, it would have been quite impossible for him to have written the report on the last census without the assistance of Dr. Tatham, of Mr. Noel Humphreys, and of Mr. Waters. Referring to the declining birth-rate, the Registrar-General said that he did not hold the pessimistic views which were attributed to some persons. He certainly did not consider that England was going downhill.

Dr. TATHAM, in response, said that when he realised the import of the presence of so many eminent public health officers, he was impressed with the fact that he never knew that he had so many sympathetic friends. He felt that he did not owe the honour that had been done him to any merits of his own, but rather to the general feeling of comradeship that existed between members of the medical profession and himself. Statistics, he said, must be more or less defective, but his aim had always been to reduce their defects to a minimum. Speaking with an experience of 16 years, he could still express a very high opinion of the value of the certification of the cause of death by medical men, and the replies to the 5000 letters of inquiry which were sent out each year from the General Registry Office with a view of clearing up doubtful statements were distinctly helpful in securing accuracy. When compared with the statistics of foreign countries we had nothing to be ashamed of in those of our own. When appointed Superintendent of Statistics he did not sever his connexion from public health administration without much searching of heart, but his life at Somerset House had been made happier and easier from the loyal support he had received from his colleagues in the medical profession as well as from every member of the staff. He expressed the hope that his successor would be no less fortunate in this respect.

Dr. WHITELEGGE submitted the toast of "The Chairman," who responded in literally two words.

SANITATION IN INDIA.

VIII.[1]—PLAGUE ADMINISTRATION IN THE UNITED PROVINCES IN 1907.

THE year 1907 unfortunately gave a very severe recrudescence of plague after the comparative lull of the previous year, and although the mortality figures did not reach those of 1905, yet the months of March, April, and May witnessed the severest epidemic that has yet visited these provinces, no less than four-fifths of the total mortality of the year *occurring in these three months.* The total number of cases was 257,666, as against 58,489 and 305,737 of the two preceding years. The highest mortality occurred in April, reaching 85,979 cases. The epidemic thus reached its zenith somewhat later than usual, and lingered *somewhat* longer into May and June. Only two districts remained free from the epidemic, 46 out of 48 being more or less severely attacked. The noteworthy features of the epidemic were the above severe mortality in March, April, and May, its later course thus approximating more closely as *regards season to the ordinary Punjab type,* and also the absence of any severe recrudescence in the last three months of the year. With regard to the cause of the latter feature, various hypotheses can be put forward, such as the higher degree of immunity prevailing amongst the rats, consequent on the severity of last season's disease, the same severity having diminished their numbers, or these rodents were unable to find a sufficiency of food in the vicinity of man owing to the famine; again, owing to drought there was in all probability a diminished *prevalence of fleas.* Lastly, the people may have become more sensibly inclined to the prophylactic measures of rat killing, evacuation, and inoculation. The severe and later extending mortality from March to May may be partially explained by the exceptional mildness of the early part of the hot weather. The methods now relied on in dealing with outbreaks are evacuation and inoculation; these will *undoubtedly stop any epidemic if applied rapidly* and efficiently. Disinfection is not now insisted on, as the benefit ensuing is not commensurate with the inconvenience involved, and if used as a substitute for evacuation it is useless, and if in addition to it unnecessary. Where asked for, however, an emulsion of kerosine oil—"Plunas"—is recommended. The chief feature of the plague policy of 1907 has been the attempt to popularise inoculation. Major J. Chaytor White, I.M.S., to ensure this visited the headquarters of most of the districts and lectured on the disease and its prevalence, giving spec[illegible] inoculations, showing how tl[illegible] precautions were taken to [illegible]uring the year 34,168 inoculations were performed; only nine of those inoculated have died from plague. A memorandum [illegible] last August giving many notable instances of [illegible]od. The prejudice against this measure is evidently breaking [illegible]scence of the disease appeared the chief plague officer, Captain R. F. Baird, I.M.S., considers that thousands would have been [illegible] the hundreds who have actually submitt[illegible] Regarding the duration of the protecti[illegible] conferred by inoculation, it certainly lasts through the succeeding year's epidemic, and some degree even remains after an interval of five years. Thus the benefit may remain after several years. The general impression that the protection lasts only from six months to a year and then quickly vanishes is erroneous. Other methods of prevention were also carried out—namely, sanitary inspection and an energetic campaign against rats by traps and poisoned baits, the trap recommended being the "*wonder*" and the poison "the common-sense" poison.

Lastly, we may mention that the Advisory Committee on plague *investigations* in India states that, as the result of a large number of experiments, it has been determined that though plague may be communicated to rats by feeding them on large quantities of infected material, yet that in nature this rarely or never occurs, and *that rats do not* become infected by eating their dead fellows; that plague bacilli [illegible]imentary canal [illegible] pass out in the [illegible]ealthy animals. The flea, however, is merely a passive transmitter of the disease. This well-written report on plague in the United Provinces reflects the highest credit on its author, Captain Baird, the chief plague officer of the Provinces.

VACCINATION.

Burma.

Major O. E. Williams, I.M.S., the Superintendent-General of Vaccination, furnishes the report concerning this measure for Burma for 1907. It would appear that many serious defects which have been brought to notice in previous reports still persist, although the work of the vaccination department in the last three years shows much improvement. The total increase in the number of operations in the province outside Rangoon is only some 11,000 per annum, and the number of *successful vaccinations is still about 30 per 1000 of the* population. The average number of operations performed by each vaccinator was actually less than the average of the last triennium. The difference in results in adjoining districts, where the conditions of work are similar, is striking. Thus there were 3100 a year in the Sagaing district, against only 1200 in Shwebo, and again 1300 operations in both Bassein and Myaungmya, against 550 and *390* respectively for Ma-ubin and Pyapôn. This difference is in part attributed to inefficiency and want of tact on the part of the vaccination staff. Inoculation is still practised freely in rural areas and is reported to have caused outbreaks of small-pox in certain districts. A Bill will shortly be introduced to prohibit inoculation in any rural area, but the operation of this Bill will be at first introduced only where the vaccination department is rendered thoroughly efficient. In order to provide for better supervision the service of native superin*tendents has been reorganised and enlarged from 16 to 44.* Major Entrican, I.M.S., receives well-deserved praise for his work at the vaccination depôt. In Rangoon a serious outbreak of small-pox in 1905–06 resulted in a great excess of work, [illegible] been performed in the triennium [illegible] as compared with 44,000 in the [illegible] notice with much pleasure that *the proposed portable haversack for vaccinators, alluded to* in last year's vaccination note, has been greatly elaborated. The haversack and its contents are the joint result of the labours of the Deputy Sanitary Commissioner and of Captain R. D. Saigol, I.M.S., the best features of whose separate designs this equipment combines.

Bengal.

The seventh triennial report of vaccination in Bengal for the years 1905–06, 1906–07, and 1907–08 is presented by the Sanitary Commissioner for Bengal, Lieutenant-Colonel F. C. Clarkson, I.M.S. *The total number of operations performed* in the province during 1907–08 was 2,058,371, against 2,037,273 in 1906–07 and 2,041,230 in 1905–06. There was an average increase of 279,678 cases. This increase is very satisfactory in view of the adverse circumstance existing, such as scarcity, in many parts of the province. The [illegible] of success was also marked, being 99·22 and 69·97, [illegible] *98·77 and 61·94 of 1903–05, for primary* vaccina[illegible]nd revaccination. The results, indeed, would have been far better still had it not been for the scarcity existing in the province, which made the poor people reluctant to offer their children for vaccination during the year owing to their inability to pay the vaccinators' fees. Several useful reforms have been introduced into the department, tending to better work and *greater efficiency, such as the following:* increase of pay of the subordinate inspecting staff with a view to secure greater efficiency; better education of the inspecting staff and the vaccinators; general introduction of antiseptic vaccination throughout the province (this has been attended with beneficial results, there being a general diminution of sore-arm); general introduction *of the system of grants of rewards to vaccinators; general* introduction of lanoline lymph in the districts comprised within the Bengal and Orissa circles; supply of lymph direct [illegible] adopted for pushing on vaccination in Orissa. Here there had been an *abnormally high mortality from small-pox for years* past, which was discovered to be mainly due to the backward state of vaccination, resulting from the opposition to the operation. Steps have now been taken, due to the intervention of Colonel Clarkson, whereby the civil surgeon is furnished with the tour programme of the district magistrate, so that the subordinate vaccination inspecting officers may appear before him in the mufassal and invoke his aid when necessary. A perusal of this interesting report shows how thoroughly the Sanitary Commission for Bengal is directing the vaccination department.

---

[1] Nos. I., II., III., IV., V., VI., and VII. were published in THE LANCET of April 10th (p. 1067) and 24th (p. 1199), May 1st (p. 1269), 15th (p. 1412), and 22nd (p. 1480), June 5th (p. 1630), and 19th (p. 1773) respectively.

With this article we conclude our summary of the reports which have reached us from different Government departments of India during the past few months. The reports mostly deal with the sanitation of India (including Burma) during 1907, and show the mass which has to be done and the valiant way in which the strife to do it is carried on. We wish it were possible to put the results of this excellent work before our readers at a date somewhat nearer the time of its performance, but we cannot review the reports before we get them.

METROPOLITAN HOSPITAL SUNDAY FUND.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 25th, 1831.

PHYSIOLOGY OF PARASITIC ANIMALS.

THEIR FREQUENT OCCURRENCE IN MACKEREL.

To the Editor of THE LANCET.

SIR,—As the subject of parasitic animals is one of peculiar interest, and as any observations tending to throw light on their, as yet obscure, physiology, cannot fail of proving useful, I have troubled you with the few following remarks, thinking you might find them of sufficient interest for insertion in your Journal.

I would wish particularly to direct the attention of those who are engaged in the study of this subject, to the extraordinary manner in which the common mackerel is infested with parasitic animals. Having dissected several last summer, and during the present season, at first for a different purpose, I find them so generally infested, that it is rare to meet with one free from the disease. On examining one of these fish, several worms of the *filaria* description, varying in number from five to fifty, will be found within the abdominal wandering between the convolutions of the intestin other viscera, and confined entirely within sac, the surface of which seems well exudation.

A further examination will show, in a most the origin of these worms, and that they from the intestinal cavity, which indeed The peritoneal surface bears no marks of animals, but on several parts of the beneath it, and principally between forming the mesentery and mesopuscles of an opaque, fuscous colour, about that of a pin's head; these or cyst, the smallest containing only with mucus, but in the larger and worm may be distinguished in a are evidently the ova, from which abdomen are produced; nor can generation be more apparent.

[illegible] ive not a similar [illegible] taken in with the [illegible]

Rudolphi, in his great [illegible] having observed in dissect [illegible] the villous coat of the [illegible] resemblance to the head of a variety of tænia, two or three of which were in the alimentary canal, but I believe the intestines have not often been examined with this view.

With respect to the worms found in the mackerel, I may merely mention that their organisation is exceedingly simple; [illegible] they are very tenacious of life, continuing in active motion in water for a day or two after removal from the fish.

I will not trespass further than to observe that though, as I mentioned above, the prevalence of this disease in mackerel is very general, and in some very extensive, I have not witnessed any decided ill effects having arisen from the use of this fish as an article of food, but have reason to think some caution in this respect to be necessary. I have once, only, observed trout to be similarly affected.

I remain your obliged,

18, Salisbury sq, June 9, 1831. H. PEACOCK, Surg.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Presidential Address.—Annual Dinner.

A MEETING of this society was held on June 18th, Professor RONALD ROSS, the President, being in the chair.

Professor Ross, in the course of his presidential address, said that the failure of nations was often ascribed to many causes, but too seldom it was referred to one which might be a predominant cause—namely, endem[illegible] told them of whole races of a [illegible] archæology of whole civilisations [illegible] tained that the disease factor in such events had probably been more potent than hitherto had been admitted After pleading for a fuller consideration of the scientific history of tropical medicine than was now the case, Professor Ross considered in detail the question of including in the general medical curriculum more instruction in parasitology and in medical entomology, and discussed the defects in sanitary practice, dealing especially with the housing of natives in [illegible] itary organisation.

[illegible] inner of the society was [illegible] London, when the President occupied the chair. Dr. W. Carnegie Brown, who was responsible for the arrangements of the dinner, received many congratulations on the success of his efforts. Colonel Seely, M.P., in the course of an eloquent speech proposing "Success to the Society," described the results of the work of the society as amazing, and instanced as an example the reduction of the ravages of sleeping sickness to one-tenth of what they had been. Other speakers included Sir Alfred Jones, Sir Rubert Boyce, Sir Patrick Manson, Sir Archibald Geikie, Mr. Henry Morris, Count Mörner, and Mr. Ramsay Macdonald, M.P.

EPSOM COLLEGE.

AT the annual general meeting to be held at the office in [illegible] votes, and be declared to have been duly elected:—

Pensionerships.

Public Health.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Sanitary Circumstances and Enteric Fever Prevalence in the County Borough of Rotherham.—Dr. R. D. Sweeting gives a somewhat unfavourable report on the sanitary condition of this important Yorkshire town and shows that its public health administration leaves much to be desired. Rotherham is an industrial and mining town adjoining Sheffield, with a population which is now estimated at 64,000 and is contained in some 12,500 houses. It attained the dignity of a county borough in 1902 after inquiry into its sanitary circumstances had been made by the Local Government Board, and certain improvements had been outlined or promised by the local authority. Some important powers for this purpose were obtained by the Rotherham Corporation Act of 1904, which among other matters enabled the corporation to require conversion of the objectionable privies of the place into water-closets. Large sums have been expended for sewerage purposes in recent years, and arrangements have been made by which Rotherham has been able to draw on the Sheffield water-supply and so to abandon some unsatisfactory sources of water on which the town was formerly dependent In future both Sheffield and Rotherham will share in the large new Derwent scheme of water-supply which is now in course of completion. The medical officer of health, who was formerly only engaged to give occasional services, has since 1906 been appointed to give his whole time to official work. A woman health visitor has been appointed and has done good work, the results of which can be clearly traced in the reduction of infantile mortality in the families visited A satisfactory isolation hospital has been built during the last few years. The total indebtedness of the borough under the Public Health and local Acts is high and amounts to over £750,000. But, notwithstanding this expenditure, part of which has been for sanitary purposes, and the various improvements above referred to, the borough shows evidence of insufficient sanitary administration and supervision in many directions, and remains characterised by excessive mortality from enteric fever when compared with other large English towns. This has averaged 0·19 per 1000 for the 16 years 1892 to 1907, and only in one of these years has been below 0·10 per 1000. The diarrhœa death-rate has been likewise excessive throughout this period The report gives an account of inquiries into the endemic enteric fever of the borough, and Dr. Sweeting points to the conditions which appear specially to have favoured its local prevalence. There is much insanitary house property, consisting largely of back-to-back houses; [illegible] of speci[illegible] ashpit c[illegible] hood of [illegible] pigs an[illegible] insuffici[illegible] and re[illegible] in some [illegible] respect to them are not enforced. Certain streets are "unmade" and in a constantly filthy condition. Dr. Sweeting emphasises the recurrence of enteric fever in these circum[illegible] years; (*b*) in the [illegible] same houses in [illegible] he operation of [illegible] prevalence, and very few instances of multiple cases in families which could be explained on a thesis of personal infection An unusual proportion of recently notified cases has consisted of children of school age, and in regard to some of these the diagnosis appeared open to doubt Medical practitioners are invited to submit blood serum of their patients for examination by the medical officer of health, but few avail themselves of this offer Dr. Sweeting evidently considers that much of the inefficiency which exists in the everyday working of the sanitary administration in Rotherham is to be attributed to the unsatisfactory system by which the inspectors in the public health department are permitted to carry out their duties practically independently of any directions by the medical officers of health, and his report concludes with a series of recommendations on this and other matters.

past, which was discovered to be mainly due to the backward state of vaccination, resulting from the opposition to the operation. Steps have now been taken, due to the intervention of Colonel Clarkson, whereby the civil surgeon is furnished with the tour programme of the district magistrate, so that the subordinate vaccination inspecting officers may appear before him in the *mufassal* and invoke his aid when necessary. A perusal of this interesting report shows how thoroughly the Sanitary Commission for Bengal is dire[illegible] the vaccination department.

With this article we conclude our summary of the re[illegible] which have reached us from [illegible] departments of India during the pa[illegible] mostly deal with the sanitatio[illegible] during 1907, and show the m[illegible] the valiant way in which the [illegible] carried on. We wish it were possible to put the results of this excellent work before our readers at a date somewhat nearer the time of its performance, but we cannot review the reports before we get them.

[illegible] communication of the council. The Cambridge health visitors have collected some valuable material with regard to the feeding of infants in relation to epidemic diarrhœa, and this may be summarised as follows. Among 1219 entirely breast-fed children there were two deaths, or 0·16 per cent.; among 361 partly breast-fed there were 13 deaths, or 3·6 per cent.; and among 250 non-breast-fed there were 22 deaths, or 8·8 per cent. The influence of the health visitors in the direction of inducing proper recovery of the mothers after confinement is well brought out by the following figures. In 1906 and 1907 only 32·3 and 32·5 per cent. of the mothers stayed in bed over ten days after confinement, but in 1908, owing to the efforts of the health visitors, 97·1 per cent. stayed in bed beyond this period. A steady decline in the death-rate from pulmonary tuberculosis in Cambridge has been taking place for many years, and it has now been decided to make an attempt to hasten that decline by admitting some advanced cases into the isolation hospital. As bearing upon the question of school-induced diphtheria, it may be noted that 41 cases in 25 households "were possibly the direct result of school assemblage." Enteric fever has shown a marked decrease during the last six years, and the six cases notified in 1908 were all probably imported. Dr. Laird makes but few comments upon the water-supply of Cambridge. He tells us, however, that the town council has taken steps to have daily bacteriological examinations of the water made, and has approached the water company in connexion with the valuable and eminently cautious report made by Dr. Theodore Thomson and Mr. P. W. Crosthwaite to the Local Government Board. The town council is, we are told, now "anxiously awaiting the decision of the water company as to what steps they intend taking in order to eliminate the possibilities of contamination to which the Board's report refers." No reference is made in the interesting report before us to the sanitary condition of any of the Colleges of this great University, and we are wondering whether this absence of comment is to be taken as a tribute to the excellency of the supervision exercised by all the College authorities.

County Borough of Hanley.—Successful attempts have been made in this borough to diminish the amount of black smoke, several of the large manufacturers having taken active steps to minimise the nuisance, with the result that incidentally they have found a saving in expenditure on fuel. The firemen have themselves taken great interest in the methods introduced, which have caused no inconvenience to the manufacturers. There were 165 cases of diphtheria notified during 1908 with only five deaths, and amongst the preventive

in one family during the same week, five persons being attacked. Unfortunately, the precise source of the mischief was not determined. On Saturday, Oct. 3rd, one and a [illegible] pounds of pressed tongue and pig's cheek purchased in [illegible] town were consumed by a family of five persons, and the meat was eaten for dinner on the same day. On [illegible] the father, one daughter, and one son were all taken ill, the younger son suffered but slightly, and the mother escaped entirely. Part of the tongue did not taste good and was given to a dog which was also taken ill. It is of interest [illegible] observe that although dogs are accustomed to eat offal [illegible] various descriptions two of them in the cases recor[illegible] above manifested symptoms of poisoning. Dr. F. B[illegible] Phillips, the medical officer of health, has been [illegible] ing to abolish the fair which is held in Bedford [illegible] weekly. He points out that owing to the large number of children in the town for educational purposes all [illegible] risks of infection should be done away with.

City of Coventry.—The death-rate from pulmonary tuberculosis in this city, with its population of 91,000, has [illegible] steadily declining since 1875, and the [illegible] recently been considering the question of utilising [illegible] existing small-pox hospital as a sanatorium. But [illegible] medical officer of health, Dr. E. H. Snell, and the engineer [illegible] after carefully examining the institution, came to the [illegible] clusion that it was not well adapted for a sanatorium [illegible] as regards its site, its soil, its arrangement, or its [illegible] the city, and subsequently the sanitary committee [illegible] the idea of making use of the institution. On the other hand, it has determined to rent six beds at the Winsley [illegible] near Bath, at the rate of £100 per annum per bed, and [illegible] medical practitioners in the city have been notified of the arrangement. These municipal beds are intended for [illegible] and possibly curable cases of pulmonary or [illegible] culosis, and they [illegible] can afford to go [illegible] idea [illegible] paupers. Each [illegible] with a certificat[illegible] and the medica[illegible] re[illegible] referee. We ar[illegible] be no doubt that [illegible] to glad to be spare[illegible] patient in whon[illegible] no fixed limit to the period of stay in this [illegible] Certainly all experience points to the fact that three [illegible] is usually too short, and it is far better to [illegible] of the matter in the hands of the medical superintendent of the sanatorium. We trust that the after-result statistics [illegible] be so kept and recorded that the people of C[illegible] may be able to appreciate the precise value of the provision made. We believe that the city of Bath, which also contributes to this institution, has arranged to have the figures for each year kept separately so as not to present the after-results in a too optimistic fashion. Dr. Snell has been appointed school medical officer for Coventry, the actual inspection being carried out by an assistant medical officer whose work is facilitated by a nurse. It seems that in the case of Coventry the children are not all examined at the schools at which they attend, but that certain schools have been fixed upon as "centres." With reference to the important subject of treatment, Dr. Snell points out that the agencies available consist of the usual complement of private medical and dental practitioners, while to meet the needs of those who are unable to pay full medical fees there are many medical men whose services are available through the channel of clubs and friendly societies. For those who are too poor to pay anything there are four district medical officers, the Poor-law infirmary, and the Coventry and Warwickshire Hospital. But in spite of these several provisions there are, Dr. Snell adds, certain defects for the treatment of which there are not as yet adequate arrangements. He instances defective vision, defective teeth, and ringworm. As regards the first, he reports that the relatively small number whose defects have been attended to have found their way to the eye department of the local hospital, which institution has represented to the education authority the manner in which the resources of the eye department are being taxed by the attendance of school children requiring prescriptions for spectacles. As to dental treatment, the dental department of the same institution finds that the extractions required are so numerous that general conservative treatment would be impracticable with the present resources. Finally, with respect to ringworm, Dr. Snell thinks that if the x ray treatment is undertaken it should be placed in the hands of some medical practitioner who should use drugs or x rays at his discretion, according to the severity of the case.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8647 births and 3880 deaths were registered during the week ending June 19th. The annual rate of mortality in these towns, which had been equal to 12·3 and 12·6 per 1000 in the two preceding weeks, declined again to 12·3 in the week under notice. During the first eleven weeks of the current quarter the death-rate in these towns averaged 14·4 per 1000; the mean rate in London during the same period did not exceed 13·8. The lowest recorded annual death-rates in these towns last week were 4·5 in East Ham, 5·6 in Leyton, 6·0 in Hornsey, and 6·4 in King's Norton, all being suburban districts; the rates in the other towns ranged upwards, however, to 17·9 in Salford, 18·9 in Norwich, 19·2 in Rochdale, and 25·4 in Great Yarmouth. In London the recorded death-rate last week did not exceed 11·4, a lower rate than in any previous week of this year. The 3880 deaths from all causes in the 76 towns last week showed a decline of 83 from the number in the previous week, and included 364 which were referred to the principal epidemic diseases, against 362 and 393 in the two preceding weeks; of these 364 deaths, 173 resulted from measles, 57 from whooping-cough, 55 from scarlet fever, 35 from diarrhœa, 28 from diphtheria, and 16 from "fever" (principally enteric), but not one from small-pox. The 364 deaths from these epidemic diseases last week were equal to an annual rate of 1·2 per 1000, against 1·1 and 1·2 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Willesden, Birkenhead, South Shields, Hornsey, or in ten other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·8 in Liverpool, 4·5 in Salford, 5·0 in Wolverhampton, and 8·4 in Norwich. The fatal cases of measles in the 76 towns, which had been 140 and 186 in the two preceding weeks, declined again last week to 173; the fatal cases of this disease caused annual death-rates last week ranging upwards to 2·2 in Salford and in West Bromwich, 5·0 in Wolverhampton, and 8·4 in Norwich. The 57 deaths from whooping-cough exceeded the number in the previous week by two, and included 24 in London and its suburban districts, five in Manchester and Salford and three in Cardiff. The 55 fatal cases of scarlet fever showed a further increase upon recent weekly numbers, and exceeded the number returned in any previous week of this year; the highest rates from this disease last week were 1·1 in Blackburn, 1·3 in Merthyr Tydfil, 1·5 in Wallasey, and 2·2 in Warrington. The 35 deaths attributed to diarrhœa showed a marked decline from the numbers in recent weeks, as did the 28 deaths from diphtheria; the fatal cases of the latter disease included six in Manchester and Salford, and five in Liverpool. The 16 deaths referred to "fever" were again considerably below the corrected average. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 2223 and 2263 at the end of the two preceding weeks, had further increased to 2445 on Saturday last; 468 new cases of this disease were admitted to these hospitals during last week, against 275 and 305 in the two preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 225, 172, and 152 in the three previous weeks, further declined to 135 in the week under notice, and were 18 below the corrected average number in the corresponding week of the five years 1904–08. The deaths in London directly referred to influenza declined last week to six, against ten and 13 in the two previous weeks. The causes of 35, or 0·9 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. The causes of all the [illegible]

[illegible] the 76 towns included four in [illegible] and three in Gateshead, in [illegible]

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 1010 births and 554 deaths were registered during the week ending June 19th. The annual rate of mortality in these towns, which had steadily declined in the four preceding weeks from 17·5 to 14·5 per 1000, rose again to 15·5 in the week under notice. During the first eleven weeks of the current quarter the death-rate in these Scotch towns averaged 16·5 per 1000, while in the 76 large English towns the mean death-rate during the same period did not exceed 14·4. The death-rates last week in these Scotch towns ranged from 8·5 and 10·1 in Perth and Greenock to 16·9 in Glasgow and 18·7 in Paisley. The 554 deaths from all causes in the eight towns showed an increase of 36 on the low number returned in the previous week, and included 56 which were referred to the principal epidemic diseases, against numbers declining from 76 to 55 in the four preceding weeks. These 56 deaths were equal to an annual rate of 1·6 per 1000, against rates declining from 2·1 to 1·5 in the four previous weeks; the mean death-rate last week from these principal epidemic diseases in the 76 large English towns did not exceed 1·2 per 1000. Of the 56 deaths from these epidemic diseases last week in the Scotch towns, 18 resulted from whooping-cough, 13 from measles, 13 from diarrhœa, and four each from scarlet fever, diphtheria, and "fever," but not one from small-pox. The fatal cases of whooping-cough in the eight towns, which had declined from 40 to 22 in the four preceding weeks, further declined last week to 18, of which 11 occurred in Glasgow and five in Edinburgh. The 13 deaths from measles, however, showed a marked excess upon recent weekly numbers, and included 10 in Paisley. The 13 deaths attributed to diarrhœa were within two of the number in the previous week; seven occurred in Glasgow and two both in Aberdeen and Paisley. Three of the four deaths from scarlet fever were returned in Glasgow, as were all the four fatal cases of diphtheria. The four deaths referred to "fever," of which three were certified as cerebro-spinal meningitis and one as enteric, were also all recorded in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had steadily declined in the four preceding weeks from 109 to 80, further declined last week to 73, and corresponded with the number in the corresponding week of last year. Of the deaths in the eight towns last week, 16 resulted from violence, including seven in Glasgow, six in Edinburgh,

* Including membranous croup.

and two in Aberdeen. The causes of 19, or 3·2 per cent., of the deaths in the eight towns last week were unspecified or uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 18·2 and 18·7 per 1000 in the two preceding weeks, declined to 15·7 in the week ending June 19th, and was considerably lower than in any previous week of this year. During the first 11 weeks of the current quarter the death-rate in the city averaged, however, 21·2 per 1000, whereas the mean rate during the same period did not exceed 13·8 in London and 16·3 in Edinburgh. The 120 deaths of Dublin residents from all causes during last week showed a decline of 23 from the number in the previous week, and included ten which were referred to the principal epidemic diseases, against 11 and nine in the two preceding weeks. These ten deaths were equal to an annual rate of 1·3 per 1000, the death-rate from these epidemic diseases in the same week being but 1·0 in London and in Edinburgh. Of the ten deaths from these epidemic diseases in Dublin last week, three resulted from measles, three from whooping-cough, three from diarrhœa, and one from "fever," but not one either from scarlet fever, diphtheria, or small-pox. The fatal cases of whooping-cough showed a further decline, while those of measles and diarrhœa were more numerous than in recent weeks. The 120 deaths included 20 of infants under one year of age and 32 of persons aged upwards of 60 years; both these number showed a decline. One inquest case, but no death from violence, was registered during the week; 43, or 35·8 per cent., of the deaths occurred in public institutions. The causes of all but one of the deaths in the city last week were duly certified by a registered medical practitioner or by a coroner; in London the causes of all but one of the 1060 deaths last week were also duly certified, whereas in Edinburgh the proportion of uncertified causes of death was equal to 5·4 per cent.

VITAL STATISTICS OF LONDON DURING MAY, 1909.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City
of London and in each of [illegible] With
regard to the notified cas[illegible] pears
that the number of pers[illegible] from
one or other of the nine [illegible] was
equal to an annual rate [illegible] tion,
estimated at 4,833,938 persons in the middle of the year; in the three preceding months the rates were 6·4, 5·9, and 5·4 per 1000 respectively. The lowest rates last month were recorded in Kensington, Fulham, St. Marylebone, Hampstead, and Southwark; and the highest rates in Paddington, Chelsea, Bethnal Green, Greenwich, Lewisham, and Woolwich. The prevalence of scarlet fever showed a marked increase last month; among the various metropolitan boroughs
this disease was proportionally [illegible]
Hammersmith, Chelsea, the [illegible]
Green, Greenwich, Lewisham, [illegible]
politan Asylums Hospitals [illegible]
patients at the end of last [illegible]
2143 at the end of the three preceding months; the weekly admissions averaged 318, against 283, 278, and 262 in the three preceding months. Diphtheria was somewhat less prevalent than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Chelsea, Finsbury, Shoreditch, Bethnal Green, Greenwich, and Lewisham. There were 920 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 1152, 1103, and 1012 at the end of the three preceding months; the weekly admissions averaged 108, against 133, 121, and 109 in the three preceding months. The prevalence of enteric fever again showed a slight increase over that recorded in the preceding month; this disease was proportionally most prevalent in Paddington, Fulham, Chelsea, Islington, Shoreditch, and Bethnal Green. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 124, 87, and 57 at the end of the three preceding months, had further declined to 49 at the end of last month; the weekly admissions averaged eight, against nine and seven in the two preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Stepney, Bermondsey, and Deptford. The 21 cases of puerperal fever notified during the month included two each in Hammersmith, Islington, Shoreditch, Wandsworth, and Deptford. Of the four cases notified as cerebro-spinal meningitis, two belonged to Lambeth, and one each to Hampstead and Wandsworth.

[illegible]
resided. During the four weeks ending May 29th the deaths of 4793 persons belonging to London were registered, equal to an annual rate of 12·9 per 1000; in the three preceding months the rates were 18·5, 21·4, and 15·0 per 1000. The lowest death-rates last month were 8·7 in Hampstead, 9·4 in Lewisham, 9·6 in Stoke Newington, 9·7 in Fulham and in Greenwich, and 10·2 in Wandsworth; the highest rates were 16·9 in Bermondsey, 17·7 in Poplar, 19·2 in Shoreditch, 20·8 in the City of London, and 21·1 in Finsbury. The 4793 deaths from all causes included 518 which were referred to the principal infectious diseases; of these, 241 resulted from measles, 33 from scarlet fever, 53 from diphtheria, 138 from whooping-cough, eight from enteric fever, and 45 from diarrhœa, but not any from small-pox, from typhus fever, or from ill-defined pyrexia The lowest death-rates from these diseases last month were recorded in Kensington, Chelsea, St. Pancras, Holborn, the City of London, Greenwich, and Lewisham; and the highest rates in Hammersmith, Finsbury, Shoreditch, Poplar, Southwark, and Bermondsey. The 241 fatal cases of measles were 29 in excess of the corrected average number for the
correspondin[illegible] years; the greatest
proportional [illegible] was recorded in
Hammersmit[illegible] ney, Poplar, and
Bermondsey. [illegible] t fever showed a
slight decline from the corrected average number; this disease was proportionally most fatal in Hammersmith, Fulham, the City of Westminster, Poplar, Deptford, Greenwich, and Woolwich. The 53 fatal cases of diphtheria were 19 above the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, Fulham, the City of Westminster, Shoreditch, Lambeth, Battersea, and Lewisham. The 138 deaths from whooping-cough were 25
fewer [illegible] number for the correspond-
ing pe[illegible] s; the greatest propor-
tional [illegible] recorded in Hammer-
smith, Finsbury, Shoreditch, Poplar, Southwark, and Bermondsey. The eight fatal cases of enteric fever showed a marked decrease from the corrected average number; these eight deaths included two in Islington, two in Poplar, and one each in Fulham, Bethnal Green, Lambeth, and Wandsworth. The 45 deaths from diarrhœa were 14 below the corrected average number; this disease was proportionally most fatal in Hammersmith, Fulham, St. Marylebone, Finsbury, Shoreditch, Poplar, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases corresponded with the average mortality in the same period of the five preceding years.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 94 per 1000. The lowest rates of infant mortality were recorded in Fulham, Hampstead, Stoke Newington, Holborn, Wandsworth, Lewisham, and Woolwich; and the highest rates in Hammersmith, Finsbury, the City of London, Shoreditch, and Poplar.

DONATIONS AND BEQUESTS.—By the will of the [illegible] eive
late Dr. John Hall [illegible] bout
£1000, and each of [illegible] lent

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: M. J. Laffan, to the *Implacable;* F. E. Bolton, to Chatham Hospital; and J. Glaister, lent, the *Circe*, for manœuvres.

ROYAL ARMY MEDICAL CORPS.

Captain T. J. Potter, from Belfast, has been appointed for duty in the London District. Major A. G. Thompson has been appointed to the charge of the Brigade Laboratory at Ferozepore. Captain A. H. Safford has been appointed to the charge of the Brigade Laboratory at Fyzabad. Colonel L. E. Anderson, principal medical officer, Fyzabad Brigade, will officiate as principal medical officer of the 8th (Lucknow) Division during the absence on leave of Surgeon-General P. M. Ellis.

Supplementary List.—Robert Magill to be Lieutenant (on probation) (dated June 7th, 1909).

INDIAN MEDICAL SERVICE.

The King has approved of the following promotion in the Indian Medical Service:—To be Colonel: Lieutenant-Colonel Robert Neil Campbell (dated April 2nd, 1909).

The King has also approved of the retirement of Lieutenant-Colonel William St. John Richardson (dated April 22nd, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Highland Field Ambulance: Captain John W. Milne resigns his commission (dated April 30th, 1909).

1st Home Counties Field Ambulance: Sidney Wood Milner to be Lieutenant (dated March 29th, 1909).

Sanitary Service: Captain William Archibald resigns his commission (dated Feb. 28th, 1909).

Lowland Mounted Brigade Field Ambulance: Lieutenant Robert Buchanan Carslaw, Transport Officer, from the Scottish Command, Glasgow Companies, Royal Army Medical Corps (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908).

3rd Lowland Field Ambulance: The undermentioned officers to be Majors: Captain Alexander M. McIntosh (dated April 1st, 1909). Lieutenant David J. Graham, from the Attached to Units other than Medical Units List, to be Lieutenant (dated July 3rd, 1908).

4th Southern General Hospital: The undermentioned are appointed officers whose services will be available on mobilisation (dated Sept. 29th, 1908):—To be Lieutenant-Colonels: Henry Davy, Edward James Domville, Edward Lawrence Fox, and James Elliot Square. To be Majors: John Mortimer, Arthur Charles Roper, Arthur Nathaniel Davis, Walter Ley Woolcombe, Robert Leonard Rutherford, Reginald Horace Lucy, William Cheyne Wilson, and Russell Coombe. To be Captains: John Wallis Gill, Charles Edward Bean, James Henry Dawe, George Frederick Aldous, Reginald Vaughan Solly, Henry Andrew, Ernest George Symes Saunders, William Crosbie Hamilton, Walter Ley Pethybridge, Gilbert James Arnold, George Calrow Sandford, Thomas Horton, Colin Dunrod Lindsey, Brennan Dyball, Charles Llewellyn Lander, George Augustus Roberts, Arthur Edmund Carver, and Ernest George Smith.

For attachment to Units other than Medical Units.—Surgeon-Captain John Graham Martin, from the 2nd Volunteer Battalion, The King's (Liverpool Regiment), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Captain William Watkin Jones, from the 3rd Volunteer Battalion, The Welsh Regiment, to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Major David Smart, from the 1st West Lancashire Field Ambulance, to be Major (dated May 8th, 1909). Surgeon-Captain William Buchan Armstrong, from the 9th (The Dumbartonshire) Battalion, Princess Louise's (Argyll and Sutherland Highlanders), to be Captain, with precedence as from July 11th, 1903 (dated May 20th, 1909). Arthur Edward Horsfall, late Second Lieutenant, 7th Battalion, The Duke of Wellington's (West Riding Regiment), to be Lieutenant (dated Feb. 13th, 1909). Edward Lucius Day Dewdney to be Lieutenant (dated March 17th, 1909). Surgeon-Captain Alexander Paul Swanson, from the 5th (Flintshire) Battalion, The Royal Welsh Fusiliers, to be Captain, with seniority as from May 23rd, 1900 (dated April 27th, 1909).

"Audi alteram partem."

MALARIA IN INDIA: WHAT CAN THE STATE DO TO PREVENT IT?

To the Editor of THE LANCET.

SIR,—In his letter published in THE LANCET of April 10th Professor Ronald Ross criticises a paper read by one of us at the Bombay Medical Congress last February. We think that some of his remarks may cause those who have not read the original paper and the discussion thereon to believe that we are attempting to obstruct the progress of anti-malarial work in this country, and since such a misinterpretation of our attitude would be detrimental to the interests of that work we beg that you will permit us to lay before your readers a complete, but necessarily much condensed, statement of the most elementary and essential features of the Indian problem. The standpoint from which the subject of the prevention of malaria in India is regarded by Professor Ross and some other critics in England differs entirely from the point of view from which it has to be approached by Indian workers who are aware of the nature and magnitude of the task to be dealt with, and we believe that if by this communication we are able to induce even a few people to survey the subject from the outlook of local knowledge and experience we shall have contributed to the discussion in a more useful manner than if we had undertaken the trivial task of replying in detail to each of the criticisms brought forward by Professor Ross. It is exceedingly easy to enumerate the different measures that research and experiment have proved to be of value in the prevention of malaria. It is exceedingly difficult when we come to actual practice to suggest a rational scheme of anti-malarial sanitation suitable for India.

In the first place we think we are justified in saying that very few realise the magnitude of the task of controlling malaria in India. It is a task vastly greater than any similar one yet attempted or likely in the immediate future to be attempted in any part of the world. As regards British territory alone, the problem relates to an area greater than Germany, France, Spain, Norway, Sweden, England, and Italy together, and to a population which, excluding Russia and Austria-Hungary, nearly equals that of the whole of Europe. A single malarious town in the Panjab (Delhi) has a population more than five times that of Panama, 30 times that of Ismailia, and 50 times that of Klang and Port Swettenham. But Delhi would form but an infinitesimal part of the Indian problem. Again, more than 262,000,000 out of the 294,000,000 inhabitants of India live in villages, of which by far the greater number contain less than 500 inhabitants. Thus it is obvious that any scheme for the mitigation of malaria in India which fails to recognise that the problem is largely one of its mitigation in small villages must be futile. Operations in connexion with towns and municipalities represent at most only a very minor portion of the task.

In a country like India financial considerations absolutely forbid the employment of operations involving lavish expenditure. It is useless to cite the operations at Panama as an example to be followed in this country, and no one would do so who realised, for example, that to deal with malaria among the small population of Panama required an annual expenditure greater than the total yearly income of the 138 largest towns in the Panjab. In Panama the vast resources of a rich nation were concentrated for a definite and important object on a small area. What we have to do in India is to find out the method which can be applied so as to confer the greatest benefit upon the greatest number. The recommendation that we should utilise simultaneously *all* methods, of anti-malarial prophylaxis, though apparently unanswerable, is in reality begging the question; it assumes that, as in the case of Panama, we are in the position to afford complete operations—that our task is a limited one well within our means. Only complete ignorance of the conditions could lead one to regard the Indian problem as being capable of such an easy solution. On the most hopeful view it can be possible for the State only very slowly to improve matters It is doubtful if more than a very few yet realise what they mean when they speak lightly of reducing (or abolishing) malaria in India. We are in the position of a man with 6*d.* who has to choose between a pair of boots and a loaf He has to put aside the thought of the boots and maintain his life for the present with the loaf. We have dealt with this point at some length because we think it very important that the issue should be clearly realised.

This brings us to a consideration of what the State can be expected to do. [illegible] examples of anti- [illegible] it is possible to r [illegible] will eventually be applied [illegible] ? Should it restrict itself [illegible] in the large cities, or in the [illegible] or only in cantonments, or [illegible] reduce mortality in the villages, which we have seen are the localities in which the vast majority of the population of India live? The answer to these questions is of the first importance. Clearly demonstrations of success in anti-larval operations cease to be of value when their cost is such as to prohibit their general employment in India.

When mosquito destruction was first advocated as a means of getting rid of malaria it was thought that in nearly all malarious places the task would be exceedingly easy and very cheap. It was obvious that if it could be shown that anopheles mosquitoes and malaria can be reduced by the efforts of a few labourers banded together to form a body styled a "mosquito brigade" this would be the only right method of reducing the disease; it would be a method capable of adoption in every malarious town and village in India. It is well known that in 1901 experiments with this method were begun by the Royal *Society's Commissioners* at Mian Mir. This place consists essentially of a group of villages very similar to those met with throughout the Punjab and in other parts of India, but it possesses advantages over other groups of villages in that it has a piped water-supply, a surface drainage system, and good roads [illegible] For these and other [illegible] that if in any part of [illegible] would be easy it would [illegible] ires as can be accomplished by "mosquito brigades" were carried out with great thoroughness from 1901 to 1903, but they did not affect appreciably either the numbers of anopheles mosquitoes or the prevalence of malaria. In 1904 the military authorities decided to continue the experiments on a much larger scale; in addition to extending considerably the work done by mosquito brigades they carried out further engineering works of surface drainage and completely abolished irrigation in the cantonment. These later efforts, like the earlier ones, have not resulted in an appreciable diminution in the prevalence of anopheles or malaria in the cantonment, and in the autumn of 1908 it was visited by an epidemic of the disease probably more severe than any previously experienced.

It is true certain demonstrations outside India have been held to establish the value of anti-larval *operations*, but they fail to help in the present problem because: (*a*) the areas dealt with have been, comparatively speaking, very small; and (*b*) the cost, in some cases several pounds *sterling per head of the population*, has been very great. The following figures illustrate these two points:—

Place	Population	Cost per head	Remarks
Ismailia.	6000–7000	6 5 frs initial. 2-3 frs. annual	Exclusive of quinine
Klang and Port Swettenham.	4000	£2 10s. initial	Exclusive of quinine
Panama	40,000	£10 per head annually.	Inclusive medical and sanitary expenditure

(*c*) In *every instance* quinine prophylaxis was very actively pushed and it is at least as likely that the reported reduction in malaria was due to this method as to the anti-mosquito operations At Ismailia, for instance, in 1903 and 1904 the cost of the quinine used prophylactically was more than 2 francs per head of the population durin produces the same effects with quinine alc (*d*) The only country where the conditi those of India is Italy; and in Italy ar have been abandoned in favour of measur has shown to be more effective.

We see, then, that anti-larval oper not easy of assured success It may, in fac established that for Indian villages and for rural condition generally anti-larval operations are not feasible. Even the small towns present much more serious problems than is [illegible] are only large villages [illegible] them could hope ever [illegible] tions or even expend a tithe of the amount required to produce any effects by operations of this kind. The majority can only imperfectly meet the expenditure on the simplest sanitary requirements.

Unless the State, then, is prepared to leave rural India altogether out of account and to risk what will be nothing more or less than an enormous experiment in regard to small towns it must turn its attention and exercise its chief expenditure in systematically endeavouring to extend the benefits of quinine Among many other advantages this system is the only one which cannot possibly be shown to be valueless by future advances in knowledge; more-moreover, it is cheap, is understood by the people, and is so willingly accepted by them that even in the present state of education they are ready to pay for it; it is the method which after much trial and experiment has been adopted on a national scale for the prevention of malaria in Italy, and *is the one which is regarded by Dr. Koch and other eminent* German scientists as far preferable to any other: it has already been tried on a small scale with success in India, and only needs to be taken up seriously and enthusiastically *to become a great power for the mitigation of malaria* in this country. What is essential, however, is that attention should not be diverted from the manifest advantages of this method by the many recommendations which are constantly being received in India to the effect that the destruction of mosquitoes by drainage operations should be the chief feature of malarial prophylaxis One can imagine, for example, how great would be the benefit to the people of Bengal if the money which it has been proposed to expend on the drainage schemes enumerated in the report of a recent drainage committee were spent upon the extension of quinine administration and the thorough organisation of a system for this purpose. On the most favourable view it is extremely doubtful whether any mitigation of malaria would result from the drainage schemes, but on any view it could not be doubted that great benefit would accrue from the expenditure of so much money on the organisation and carrying out of a proper system of quinine administration. At the present time quinine prophylaxis when employed in India is carried out in a slipshod and haphazard manner because it is felt that chief attention should be directed to anti-larval measures One has only to read reports upon cantonments by medical officers in India to realise how the insistence upon anti-larval sanitation has delayed the use of more suitable methods

One other feature in which the problem for India demands special [illegible] is our knowledge of [illegible] very limited, but we [illegible] ditions under which r [illegible] ent in ruling large sums to be immediately and blindly expended upon anti-mosquito work. It is, in fact, not true to represent the case so [illegible] is necessary [illegible] We are [illegible] rs, there are wide tracts of country where the disease, though present, is not markedly interfering with the prosperity and natural increase of the population. In such areas special action for the reduction of the prevalence of malaria is unnecessary—the disease is sufficiently dealt with by general arrangements such as are taken for the mitigation of other diseases. Secondly, there are areas where malaria is constantly present to a moderately intense degree; and thirdly, there are areas in which the disease can only be described as decimating the people and converting once populous and prosperous districts into scantily peopled and decayed ones

It is upon such areas as the last—where malaria is present in intensified and epidemic form and is acting as a pestilence that attention should be first concentrated. Such epidemics have causes which can be traced, and even at present it is known that the factor of anopheles mosquitoes is only one of many that are concerned in bringing about the epidemic result In the great industrial centres, for example, we have malarial epidemics whose immediate cause is the *immigration, under special conditions,* of non-immune people from healthy districts to foci of malaria started by this very process of immigration.[1] We need not here describe the events and conditions that are concerned in causing epidemics of malaria in such centres, nor need we mention other examples in which recent work has revealed what are the really important factors concerned. It suffices if we emphasise the fact that the prevalence of anopheles, though always important, is by *no means in every case* the most important factor to be considered.

It is not without due reason that Professor Celli lays such stress on legislative amendment of agrarian laws, and so on, that he emphasises the fact that in the Roman Campagna malaria is not a result of want of drainage, and that it is one of the diseases to be surveyed from the outlook which will give the widest possible standpoint if we ever hope to control it. No cut-and-dried scheme that is not doomed to enormous waste of expenditure can be organised at once. Each district of India is probably a problem *requiring study in itself,* study whose object is not in one sense scientific research but simply the getting of information absolutely necessary to action. We must know: (1) What parts of India are especially dangerous as foci disseminating malaria and what parts are likely to become so? (2) In what parts of India should an attack upon the disease be begun at once—that is, in what parts is the disease most seriously interfering with increase of population and general prosperity? (3) In what parts of India is it unnecessary to take special action at present? (4) What are the conditions at any place or in any tract it is desired to take in hand? For in the absence of accurate knowledge one cannot possibly decide upon the feasibility or suitability of proposed measures.

All that one can say at present is that the first step should be some sort of organisation for first inquiring into and then dealing with malaria, for bringing to notice at once the occurrence of epidemics or even for foretelling their advent, so that by action taken on such intelligence their effects may be minimised. There should exist also a definite system or code of rules for dealing with such outbreaks by the best methods. Such a code can be arrived at only by gradual experience. To attack a temporary epidemic due to temporary causes by cut-and-dried operations, to allow a focus of malaria to form as has happened recently at Bombay, and then to attempt to control it, would not be one of the blunders of such an organisation.

In conclusion, then, we have on the one hand the advice to start here, there, and everywhere in India anti-malarial campaigns essentially anti-larval in character, on the type of the operation at Panama, &c. We can only say that such advice appears to us only possible of contemplation with a superficial knowledge of the Indian problem. We, indeed, would give advice fundamentally different. We believe the Government would be wrong to adopt methods so diametrically different from those now carried on with such excellent results by the Italian Society, who in practical malarial sanitation (especially in that dealing with agrarian conditions) and in national malarial prophylaxis are far in advance of present English ideas. But for so long as anti-larval operations with their comparatively enormous expense and uncertain results form, as it were, the necessary and conventional basis for every endeavour to control malaria under every condition, for as long, we believe, will the real attack upon malaria in India be delayed. We know that the expense of anti-mosquito operations is very great and that for application to rural areas they are utterly unsuitable. At present expenditure upon such operations is not justifiable except on the view that further experiments are desirable and that the expenditure is for the purpose of these experiments. In the meantime it is desirable that attention should be concentrated upon quinine prophylaxis, in accordance with methods that experience has already shown in Italy to be best adapted for the prevention and mitigation of malaria on a national scale.

Holding such views, it is not surprising that we look upon the prominence given by Professor Ross to the necessity of anti-larval operations for India and his insistence on the simplicity of the task as prejudicial to progress, and we cannot see that by bringing forward what are to us the facts in regard to Mian Mir we are hindering advance. Our view is that by stating the truth regarding such operations we are combating to some extent the great misfortune that India has for some years laboured under from the continual advertisement of anti-larval measures as the only *right method* of getting rid of malaria. Mian Mir is to us not a test case as to whether successful anti-larval measures are *possible,* but one relating to the feasibility, even the relative advisability, of anti-larval operations as the most important line of attacking India. It is apart from useful argument to insist that Mian Mir is still inadequately drained. It is, of course, obvious that the anopheles now apparently present in undiminished numbers bred somewhere, and very likely that they bred in sheets of water during and after heavy rain. The fact that a very energetic campaign failed to control such conditions indicates an amount of difficulty in dealing with malaria under such conditions at present realised by few. Yet these conditions are, so far as we can see, not more difficult than will be met with in almost every place where malaria is severe in India. It will serve no useful purpose to gloss over these difficulties and to create the impression that the problem of malarial prophylaxis in India is a simple and easy one when it is in reality complex and difficult.—We are, Sir, yours faithfully,

S. P. JAMES, M.D. Lond., D.P.H.,

THE LONDON COUNTY COUNCIL AND THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—I think it is to be regretted that public attention should have been called to the recent decision of Great Ormond-street Children's Hospital with regard to the treatment of London County Council school children. It is the result of precipitate action on the part of the committee of management without previous consultation with the medical committee. I have drawn the attention of the medical committee to the matter, and I have no doubt that the committee of management, who have always shown themselves exceptionally responsive to the suggestions and desires of the medical staff, will reconsider the question at the earliest opportunity. I am, Sir, yours faithfully,

J. HERBERT PARSONS,
Ophthalmic Surgeon to the Hospital.
Wimpole-street, W., June 18th, 1909.

COLOUR VISION IN THE MERCANTILE MARINE.

To the Editor of THE LANCET.

SIR,—The long and interesting letter of Mr. C. Devereux Marshall in this week's issue of THE LANCET regarding the colour vision in the Mercantile Marine leads me to mention a case which came under my notice about two years ago. A young man, about 26 years of age, came to my out-patient department complaining of defective vision. Examination revealed hypermetropia of *nine* diopters. Now this man had been at sea on the big Atlantic liners for some years and had acted as look-out on most of the voyages. He complained that it was almost impossible for him after being some time on watch to discern anything distinctly at any distance beyond a ship or two's length away, and at night he was almost blind as far as look-out work went. I provided him with correct glasses, at the same time warning him of the risks he ran, to say nothing of that to the ship and passengers, as long as he continued to go to sea as a sailor. I told him there was nothing to prevent him acting as a fireman. However, he turned up again a few months ago saying that he had been at sea and had been compelled to act in the same capacities as before, but had decided at last to give "sailoring" up now altogether. What sort of a visual examination can have been held to have passed such a man *twice?* It must be, as Mr. Marshall puts it, that "candidates are ...... at the mercy of a board who seem" not possessed of "knowledge of the subject on which hey are asked to adjudicate."

TROPICAL ADENITIS AND PLAGUE.

To the Editor of THE LANCET.

SIR,—With reference to your annotation in THE LANCET f June 12th the following note bearing on the subject, hich was personally investigated, may be of interest.

In January, 1906, owing to a couple of cases of bubonic lague having occurred amongst the Lascars of a transport hich had conveyed a European regiment from the West ndies to Calcutta, the entire regiment was segregated on he maidan outside Fort William, and the men submitted o a thorough medical examination. Several suspicious cases f adenitis with slight pyrexia and malaise were detected nd placed in an isolation hospital. These cases were added o daily for about a week, and although the specific bacilli ould not be recovered, there was no doubt at the time that here was some relationship between the plague-infected ship nd the cases of adenitis, which were diagnosed and treated s pestis minor. With a small dose of not very malignant lague bacilli the European develops adenitis or pestis inor, a not uncommon affection amongst laboratory workers the tropical areas where plague is met with.

I am, Sir, yours faithfully,
E. B. KNOX, M.D. Dub., Captain, R.A.M.C.
Putney, S.W., June 19th, 1909.

HAMPSTEAD GENERAL HOSPITAL: THE MALCOLM MEMORIAL.

To the Editor of THE LANCET.

SIR,—At a meeting of the council held on Feb. 23rd last, was decided to raise a fund amongst the friends and dmirers of the late Mr. William Forrest Malcolm for the urpose of providing a suitable tribute to his memory. He as one of the founders of th
osition of treasurer from its
per
ficer
stitution in its present state of
With
that
orm of a portrait, to be paint
nd placed in the board-room of the hospital.

The council has decided that subscriptions shall be limited the sum of one guinea each, so that all may have an pportunity of showing their appreciation of Mr. Malcolm, hose loss is so deeply felt by all who knew him, and whose enerosity and goodness must be admired by many who may ot have been personally acquainted with him. To defray e cost of the painting the sum of 100 guineas will be quired. Will those desiring to contribute, kindly send eir subscription to the secretary at the hospital at their rly convenience.

We remain, yours faithfully,
EDMD. K. BLYTH,
ERNEST COLLINS,
CHAS. JOHNSTON,
R. A. OWTHWAITE
Special Committee, Malcolm Memorial
June 11th, 1909.

SALFORD GUARDIANS AND FEEBLE-MINDED IRLS AND WOMEN.—The Salford Guardians are about to ake a good move as regards the care of the feeble-minded irls and women who are now in their care or who may be so the future. One of the lady members recently moved that committee be appointed to consider the advisability of proiding a home for them apart from the workhouse. The uardians have on their hands some buildings not in use hich could be put in order and these poor creatures ccommodated and an attempt made to draw out what ental powers they possess. It would, of course, be ecessary to have a teacher trained in the care of the feebleinded, but the mover of the resolution did not think the ost would be great. The disadvantage of the scheme, as ompared with that carried out at Sandal Bridge, is, of ourse, that the inmates will be able to leave when they like, ut the hope is that they may be induced to stay in a home here they could be taught housekeeping, laundry work, ooking, and so on. The motion was carried unanimously.

PLAGUE AND CHOLERA IN RUSSIA, SIBERIA, AND THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

Plague in Jeddah.

THE outbreak of plague in Jeddah has come to an end with the approach of the hot season. The statistics of the epidemic were brought down to the week ending April 11th in my last letter on the subject.[1] In the week ending April 18th only one case and one death occurred, and in that ending April 25th there were reported one fresh case and two deaths. The present revival of the disease lasted from Dec. 12th, 1908, to April 21st, 1909; in that period 178 cases, with 160 deaths, have been recorded. Of the 178 cases only 28 were seen during life, the remaining 150 came to the knowledge of the authorities only after death. Only ten of the cases were removed to hospital; of these six are said to have recovered, thanks to the treatment by serum; six other cases in the town were submitted to the same treatment, and of these four recovered. It is noted that the large majority of cases were bubonic in character; only four pneumonic cases were seen (two in life and two after death). In the bubonic cases the buboes were most often situated in the groin.

Yanbo appears to have escaped infection on this occasion. It is interesting, however, to note that an imported case of plague occurred at the lazaret of El Tor, in a member of the crew of a ship coming from Yanbo. This ship, the s.s. *Marieut*, arrived at Tor on March 1st; the patient was a stoker; he was the only case of plague seen this season in the Tor lazaret. The ship had
a half previously; had take
(among whom no cases of
where the ship had been disinfected and had its rats destroyed by a Clayton apparatus; had then proceeded to Yanbo, but finding no pilgrims there returned to Tor, where, as just stated, the case of plague occurred. It would seem that the ship had in all probability become infected when at Jeddah and that the infection had remained latent during a month and half. If so, the incident is in every way analogous with the occurrence of cases of plague in the Thames in the autumn of 1896 on board a ship from Indian ports; and both incidents tend to show that mere quarantine, unless it be prolonged over an impossibly long period, can never suffice to prevent the importation of plague from one country to another.

Plague in Bagdad.

It will be recalled that the outbreak of plague in Bagdad appeared to have come to an end in February, and that the town was declared "clean" on Feb 23rd. But on May 5th two fresh cases were discovered; of these one occurred in the Abu Sefein quarter of the town, and the other in the Sedria quarter. In both districts (which are situated near the northern end of the town) plague was prevalent during the outbreak of last year. On May 12th three fresh cases were reported, and on the 23rd one. Since that date no further cases have been seen, and the measures which had been once more put in force upon departures from Bagdad by river and road were again suppressed on June 6th.

Plague in Bahrein and the Persian Gulf.

Outbreaks of plague have occurred more than once in
recent years in the Bahrein Islands. This group of islands is
situated on the south-western shores of the Persian Gulf and
is under British protection. The reappearance of the disease
there was reported on May 12th, when 3 cases and 2 deaths
had occurred. Down to May 15th there had been 6 cases
with 4 deaths. In the week ending May 22nd as many as
18 deaths from plague were recorded, but in that ending
May 28th (*sic*) the number of deaths fell to 3. The health of
the other Gulf ports has remained good. The only measures
ports against Bahrein have been a medical
tion of the circular concerning
plague have recently occurred
in other ports of the Persian Gulf. On April 14th a case was
landed at Muscat from the ss. *Africa* and died on the 16th.

---

[1] THE LANCET, May 1st, p. 1279.

Towards the end of the same month the ss. *Dumra* arrived at Bushire (on the Persian shore) from Basra; during the voyage three deaths from suspected plague occurred on board and another case (a sailor) was landed in the Bushire lazaret. This was a case of pneumonic plague, and the diagnosis is said to have been confirmed bacteriologically. At present only telegraphic information in regard to these occurrences has been received here.

Cholera in Russia.

The records of the cholera epidemic in St. Petersburg were brought down in my last letter to the week ending March 21st (April 3rd). Since then the returns have been as follows:—

	Cases.	Deaths.
Between March 21st (April 3rd) and March 28th (April 10th)	13	2
,, ,, 29th (,, 11th) ,, April 4th (,, 17th)	29	3
,, April 5th (,, 18th) ,, ,, 11th (,, 24th)	19	1
,, ,, 12th (,, 25th) ,, ,, 18th (May 1st)	8	2
,, ,, 19th (May 2nd) ,, ,, 25th (,, 8th)	12	6
,, ,, 26th (,, 9th) ,, May 2nd (,, 15th)	10	2
,, *May 3rd* (,, *16th*) ,, ,, *9th* (,, *22nd*)	*4*	1

Finally, on May 14th (27th), no fresh cases having occurred in St. Petersburg, the Russian authorities declared the city merely "threatened" instead of "infected" with cholera. It should be added that all the cases and deaths mentioned above were confined to the capital. The following revised figures have now been issued by the Russian authorities for the weekly records of the epidemic in St. Petersburg since its beginning in August last; the figures do not in all instances quite agree with those published week by week:—

Week ending	Cases.	Deaths.
August 30th	197	53
Sept. 6th	1805	567
,, 13th	2568	1113
,, 20th	1535	703
,, 27th	794	381
Oct. 4th	418	193
,, 11th	257	111
,, 18th	126	71
,, 25th	103	44
Nov. 1st	105	34
,, 8th	70	26
,, 15th	112	32
,, 22nd	154	45
,, 29th	171	66
Dec. 6th	120	40
,, 13th	107	38
,, 20th	121	36
,, 27th	96	40
Jan. 3rd	178	46
Jan. 10th	273	114
,, 17th	193	52
,, 24th	160	42
,, 31st	141	40
Feb. 7th	109	39
,, 14th	88	25
,, 21st	68	27
,, 28th	46	11
March 7th	42	6
,, 14th	25	5
,, 21st	10	3
,, 28th	13	2
April 4th	29	3
,, 11th	19	1
,, 18th	8	2
,, 25th	12	6
May 2nd	10	2
,, 9th	4	1

The total number of cases recorded in St. Petersburg has, therefore, been 10,287, and that of deaths 4020. The dates in the above table are all according to the Old Style.

In the letter already referred to, I drew attention to the question of the water-supply and drainage of the Russian capital; both these questions are now being seriously taken in hand by the Russian Government. A special Commission has been appointed by the Minister of the Interior to inquire into, and to report upon, the whole matter. The terms of reference to the Commission include five main headings; these are (briefly put) as follows: (*a*) system of sewers and disposal of dry refuse; (*b*) house drainage; (*c*) the water-supply of the city; (*d*) the financial aspects of the new schemes; and (*e*) laws and by-laws respecting drainage and water-supply.

Plague and the "Tarabagan Disease."

It has been known for many years past that in Eastern Siberia and Mongolia the marmot, or "*tarabagan*," suffers frequently from a fatal disease, which may be transmitted to man and produce in him symptoms indistinguishable from those of bubonic or pneumonic plague. From time to time I have published in THE LANCET abstracts of the principal communications to Russian medical journals on this subject, and have pointed out that, while clinically the "*tarabagan* disease" in man closely resembles plague, bacteriological proof that the two diseases are identical has hitherto been wanting. An article by Dr. B. A. Barykin,[2] dealing with this particular aspect of the question, is therefore of special interest. Dr. Barykin in the autumn of 1906 and that of 1907 made expeditions to certain districts known to be infected with the "*tarabagan* disease." He records the following facts (the details closely resemble those of outbreaks previously reported). From the spring to the autumn of 1906 there was a high mortality among the marmots round the *settlement of Abogaitui*, situated 30 versts from the station of "Manchuria." The inhabitants were fully aware of the danger and avoided all contact with the sick animals—with one exception. This was a Cossack, who was in indifferent health and particularly fancied the delicate flesh of the *tarabagan*. On Sept. 23rd he fell ill with the symptoms of plague and died on the 27th. The disease spread from him to others; in the end eight persons fell ill and all died; in all the symptoms were those of pneumonic plague. Necropsies were made in two cases; the organs were found to contain bacilli indistinguishable from those of plague; mice were injected with juice from the spleen of one, and died in 26 hours with all the appearances of having died from injections of Yersin's plague bacillus.

In the autumn of 1907 a large number of marmots were killed or caught by Dr. Barykin's party, and examined for the presence of disease. In one of these animals, which showed no external sign of being ill save a certain degree of general malnutrition, the spleen was found to be swollen and congested, and it contained large numbers of bacilli which presented all the morphological and cultural characteristics of plague bacilli. Later preparations of these organisms were shown to Professor Zabolotny and Professor Savtchenko, both of whom regarded them as in all probability true plague bacilli. A fortnight after the discovery of this infected animal the following incidents occurred in a district some 20 or 30 versts away. A Cossack family had settled in a lonely and isolated spot where marmots abounded. The men amused themselves with hunting the marmots, and one day killed one that showed clear signs of illness. In spite of warnings from the older men they skinned the animal; the body was recognised as unfit for food and was given to a girl, aged 13 years, to take back to the fields and throw away. This girl dragged the body (weighing about 15 pounds, it is said) after her through the grass, and returned to the settlement along the same path. She was barefooted. On the next day she fell ill, a bubo appeared in the left groin, and there were all the symptoms of an attack of plague; she died some days later. From the bubo, from a pustule on one finger, and from the spleen bacilli indistinguishable from those of plague were isolated; injected into mice they caused death in 18 hours, with symptoms of septicæmia. It was impossible to examine the body or skin of the animal. The men appear to have escaped infection. In the same autumn a guard at the station of Khara-Nor, and a Cossack woman at that of Sharasun both died from a disease resembling bubonic plague; the former had hunted marmots, the latter had skinned the dead animals. Sick marmots had been seen in the neighbourhood in both instances. In the case of the guard the organs were found to contain bacilli which microscopically were identical with those of plague. As a result of inquiries elsewhere it was ascertained that in the district round one station only—that of Tsagan-Oluevsk—ten outbreaks of this plague-like disease in man had occurred in the preceding nine years. None of them were very severe, and the people themselves took precautions to prevent its spread.

Constantinople, June 10th.

THE SCHEME FOR ENGLISH AID TOWARDS MEDICAL EDUCATION IN CHINA.

(FROM OUR SPECIAL CORRESPONDENT.)

THE reports having arrived of the meeting in the Mansion House of the China Emergency Committee, to which Sir Robert Hart lent his aid, it might be advisable to comment on the scheme from the local point of view. Those of us who are on the spot and are interested in the cause of medical education on Western lines among the Chinese, find our chief difficulty lies in the stolid indifference of the people and the greater part of the official class (roughly about eight-tenths of the latter) to the benefits of modern medicine and surgery. The foreign hospitals find most of their work lies in the treatment of surgical ailments. Among the better classes medical treatment is comparatively rarely sought, and it must be admitted that the empiric methods of the native doctors are often successful in the end. An official once told me that *his chief objection to foreign* doctors lay in the fact that their dietetic ideas were so totally different from what he had been all his life accustomed to, and that he found the regimen of milk, eggs, and cod-liver oil, which he had been ordered, nauseated him. At the Tung Wa Hospital at Hong-Kong (under Government auspices), where the patient has the option of choosing whether he will be treated on *foreign or native lines, it has* been found that, according to the returns, of 2687 who were treated in one year, 1422 elected to place themselves under foreign treatment, while 1265 chose the Chinese methods. There was a total of 884 deaths, of which 400 occurred under European treatment and 484 on the native side, but the figures lead to no deductions worth anything. The public *mortality in China is far too high for us to* stand idly aside and not use every endeavour to impart the benefits which we know Western science can bring, and the all-important consideration is as to how best to do this. And there can be little doubt that the main item must be the supply of teachers to *existing institutions*—men who can face the task of studying the language and of getting a sufficient *grasp of it to talk fluently and come into* personal contact with their students. A point of difficulty is that foreign education in China is in the hands of medical missionaries, and there are many better-class Chinese who fight shy of sending their sons to religious institutions. The native medical "profession" is not greatly respected—long ages of charlatanism have relegated it to a place analogous to that occupied in *England in the time* of the barber-surgeons, and it is not looked upon as an honourable calling to any extent. But China is changing rapidly; a few years ago a military career was looked down upon by civilian officials, whereas at present cadets are being sent from good families to become army officers. There is therefore no reason why a number of good examples of native scientific medical men should not open the eyes of the officials and people to the advantages obtainable. The Oriental makes a first-class student; he is logical, persevering, intelligent, and memorises well. Practical anatomy *is not as yet legal* in China, but teaching from models has, so far, been found satisfactory. A number of students, taught by Dr. W. W. Myers of Formosa, were recently sent from there to Shanghai to be examined. As there happened to be material available for dissection in the public mortuary, they were examined on it, and although it was the first acquaintance they had had with human dis*sections they all passed the tests most satisfactorily.*

---

[2] Russkii Vratch, April 18th, 1909.

The biggest foreign medical college is at Peking. There are also medical schools at Tientsin, Hankow, Hangchow, and Shanghai, but they a[illegible] through a whole course by [illegible] in addition to teaching, h[illegible] duties to attend to. It would therefore be advisable *for the China Emergency Committee to obtain particulars* from already established colleges as to what subjects are most urgently in need of lecturers, and having found these, to concentrate its efforts in obtaining professional men willing to sign an agreement for a sufficiently long time to repay their enforced language study period of at least one year after arrival. An experience of a few years in these *institutions will be all to the good* when the *time* comes for expansion in opening medical colleges in which, as far as the Chinese are concerned, there is no religious influence. In Peking, at any rate, the medical teaching missionaries have been broad-minded enough to forego the imposition of any religious tests on their students. Medical education is not a thing of creeds and sects, and while China is under an incalculable debt to missionary enterprise, there is room for the establishment of medical science among a large class who refrain from sending their sons to missionary schools. The past year has seen the establishment in Shanghai of a German medical *college in which* the instruction is given in German. It is well supported from the Fatherland and is in possession of a splendid equipment. Certain instrument-makers have sent out a complete supply of surgical instruments, two firms have each presented Roentgen-ray apparatus, while some booksellers have supplied a splendid library of up-to-date German medical literature, and a plentiful supply of drugs has been given by a number of drug firms to the pharmacy. The teaching staff has been formed of men specially sent out who stand high in the profession in Germany and are already making their school one of the best in the Far East. In this practical way are our T[illegible] head. Every student who will [illegible] is a Germanophile and will use [illegible] be a prescriber of German drugs, which are being imported in [illegible] that China is calling with [illegible] lanthropic charity. Such is [illegible] can oust the foreigner from her schools she will do so; she intends to follow in Japan's footsteps in this respect as soon as she conveniently can. During the past year she has dismissed the international foreign staff of the Peking Imperial University, even the Japanese professors have been sent back. As far as medicine *is concerned the more enlightened officials recognise they* have much to learn. It therefore behoves us to make use of the present opportunity for the people's sake to put her in possession of a body of well-trained Chinese medical men who will be the educators of her future students on sound lines—a question of the next ten years if one might hazard a guess from experiences of similar educational movements.

May 13th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Health of Newcastle.

[illegible] medical officer of health of New[illegible] that the death-[illegible] 17·3 per 1000 population, the lowest but one on record. The death-rate from the seven chief zymotic diseases—i.e., small-pox, measles, scarlet fever, diphtheria and membranous croup, whooping-cough, fever, and diarrhœa—was 1·32 per 1000 population, against a corresponding rate of 1·58 for the 76 largest English towns.

Vaccination Fees in Newcastle-upon-Tyne.

The question of the fees to be paid in respect of vaccinations to the officer of one of the districts in the city is still being actively discussed. It may be remembered that, as noted in these columns, the guardians recently decided by a somewhat narrow majority to retain the *old scale of payment* of 4*s.* 6*d.* per case to the officer to be appointed to a vacant district, rejecting the recommendation of their finance committee that the fee be reduced to 2*s.* 6*d.* The matter has now been taken up by the ratepayers' association, and at a meeting of this body last week a resolution was passed protesting against the action of the guardians in fixing the fee [illegible] *4s. 6d. Copies of this resolution* are to be sent to the [illegible]ocal Government Board, the district Government auditor, [illegible]nd to the board of guardians. A deputation was further appointed to wait upon the guardians in the matter.

Opening of a Sanatorium at Chester-le-Street.

A couple of years ago the Chester-le-Street local authorities were compelled by the Local Government Board and the county council to build a hospital *for the treatment of* small-pox. A building was therefore erected at a cost of £2500. Small-pox having been banished from the district it occurred to the local authorities that inasmuch as the building had never been once used for that purpose for which it was originally intended it might be utilised in another way. The building, after some alterations and a further outlay of some *five or six* hundred pounds, has now been formally opened as [illegible] of consumption, 26 beds being [illegible] h an institution being great in [illegible] be congratulated on its efforts [illegible]

Inter-university Students' Congress at Durham.

About 50 delegates from the various universities will be present at this Congress, which will commence on June 29th and continue until July 3rd. In supplement of the business sessions to be held a considerable programme of social arrangements has been made, amongst these being a reception at the *College of* Medicine on July 1st at the invitation of the President and Council of the College. In connexion with the Congress, some inter-university sports will be held in the College of Medicine athletic grounds in Newcastle.

June 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Resignation of Professor Chiene, Edinburgh.

AT a meeting of the Edinburgh University Court held on June 14th an application was submitted from Professor John Chiene for permission to retire from the chair of surgery. The court granted the request and agreed that it should take effect as from August 31st next. As was intimated recently in THE LANCET, Professor Chiene has not been in good health and on that account he had obtained leave of absence from his duties both in the University and in the Royal Infirmary. Professor Chiene is a graduate of Edinburgh of 1865. After graduation he was house surgeon to Professor Syme, and thereafter demonstrator of anatomy with Professor Goodsir. In 1882 he succeeded Professor Spence in the chair of surgery. He was for many years a popular teacher in the University. The candidates for the chair are members of the surgical staff of the infirmary. The chair is under the patronage of the Board of Curators, which at present consists of the Principal of the University, two Lords of Session, the Lord Provost, and three other representatives from the town council. At the same meeting of the University Court Professor Kirkpatrick was permitted to resign the chair of constitutional history, and Dr. Joseph Bell was appointed a curator of patronage as from Oct. 21st next, when Lord Stormonth Darling's term of office expires.

Medical Inspection of School Children in Fifeshire.

A conference was held between the Fife County Education Committee and the chairmen of school boards in the county to consider this subject. A committee, to consist of five members from Dunfermline district, five from Kirkcaldy, four from St. Andrews, four from Cupar, and two from Kinross-shire, was appointed to act along with the county committee in carrying a scheme into effect and to appoint assistant medical officers to carry it out. Dr. T. F. Dewar, county medical officer, will act as chief medical inspector, and there will be four male assistants under him and one lady medical officer for special cases. The inspection is estimated to cost 1*s.* per pupil. There are in the county (exclusive of Dunfermline burgh), 43,672 children, attending 135 schools.

Medical Inspection of Dundee School Children.

As provided by the new Education Act the Dundee school board has adopted the following scheme for the medical inspection of school children: a principal medical officer to be appointed, commencing with salary at £400, an assistant medical officer at £250, and two nurses at £70 each per annum, all being required to give their whole time to the work. With £210 for appliances, &c., the scheme will cost £1000 per annum, half of which falls to be met by Government grant.

Tuberculosis in Aberdeenshire.

At a conference of local authorities held in Aberdeen on March 12th, the question of what could be done with regard to the administrative control of pulmonary phthisis was discussed, and as a result Dr. J. P. Watt, medical officer of Aberdeenshire, has sent a circular to the medical men in the county as follows: "The local authorities within the county have had under consideration the circular of the Local Government Board, dated July 12th, 1908, dealing with pulmonary phthisis, and recommending, amongst other measures, that an endeavour should be made to isolate and treat certain cases of the disease, with the view of enabling the respective local authorities to form some idea of the extent to which provision for such cases might be required. I shall deem it a great favour if you will be so good as to fill up the accompanying schedule, and return it to me at your earliest convenience. I beg to enclose copy of a suggested scheme for dealing with pulmonary phthisis in the county, along with a statement submitted to a meeting of local authorities on March 12th, 1909, and I should be glad to know whether you would approve of such a scheme either in whole or in part. As the subject of phthisis is one in which all are interested any remarks or suggestions you may care to add will be most heartily welcome." The questions to which replies are requested are: "1. How many cases of pulmonary consumption are presently being treated by you? 2. Of these cases how many are (*a*) in the early stage; (*b*) in the advanced stage? 3. Of the early cases how many would be likely to take advantage of sanatorium treatment if offered (*a*) at a charge of 20*s.* to 25*s.* per week; (*b*) free? 4. Of the advanced cases how many are circumstanced that hospital isolation would be (*a*) advisable; (*b*) likely to be taken advantage of if offered free?"

June 22nd

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Burial of Bodies after Dissection.

THE burial of the bodies of the inmates of the metropolitan unions and the other destitute poor is a subject which is at present receiving a good deal of public attention—as is the correlated one of the accommodation and mode of interment afforded in the Catholic cemetery of Glasnevin. Both were discussed by the Dublin corporation last week and by the guardians of the North and South Dublin Unions. At a meeting of the board of the North Union held on June 16th it was proposed:—

> That as the statement of accounts of Glasnevin cemetery shows that some £1500 was invested last year, and some £1473 was received for interments, the North Dublin Union again request the cemeteries committee to receive a deputation from the board with a view to having certain grievances remedied, notably the excessive charges for burial and the system of "pit" burials

After the adoption of this motion it was moved:—

> That this board, having learned that the bodies of the poor transferred from this house to the dissecting schools do not receive Christian burial, now orders that no more dead bodies of the destitute poor go to these schools until arrangements are made for their interment in compliance with our resolution.

The originator of this motion had been convinced that "the unfortunate people buried in the 'pit' did not receive a Christian burial." The discussion was adjourned with an emphatic expression of the necessity for the fullest investigation. The subject is one of great importance to the Dublin schools of medicine.

The Belfast Harbour Commissioners and the City Council.

Under the Municipal Act of 1899 the city corporation of Belfast entered into a contract to erect purification works within three years from August, 1899. No purification works were erected, and as a result crude sewage escaped from the imperfect outfall shute and entered the Harbour Commissioners' channel, with the result that in 1905 it became necessary for the harbour board to remove it, and some 500,000 tons of crude sewage have been removed from the harbour channels at a cost of about £15,000 to the harbour board. That amount was claimed from the city council of Belfast, and the matter has been settled for £6000. A smaller sum was accepted than that claimed, it being thought that it would be unwise for two public boards, trustees for the people, to enter into litigation.

The Double Tenancy Question in Belfast.

At a meeting of the public health committee of Belfast held on June 17th the executive sanitary officer submitted a return in connexion with the number of notices served in the case of double tenancies in the various wards of the city, together with the number of tenants affected, and how many of these are females. In no case, excepting those where the entrance to the yard is in direct communication with the hall, can the upper tenant have access to the yard at all hours The entrance to the yard is either through the kitchen and bedroom on the ground floor or through the kitchen and passage, which is generally used as a scullery. The upper tenant has, therefore, to pass through some of the apartments on the ground floor, which cannot be said to be accessible at all hours. The water-supply is fixed either in the hall, kitchen, or passage leading to the yard, scullery, or yard. The rent varies from 1*s.* 3*d.* to 2*s.* 6*d.* per week for ground floor and from 1*s.* to 2*s.* per week for upstair portion. There are a total of 772 such houses in the various wards of the city of Belfast, and 263 female occupants of ground floor, 366 of first floor, and 16 of second floor, so that the total number of females occupying such tenement houses is 645 and males 942, making a total number of occupants of 1587. The total number of these houses with more than two families is 36 It is said that of 818 notices served only one case agreed in every particular with an opinion given by counsel as to the kind of a case that should be taken as a test.

Belfast and County Antrim Branch of the Medical Benevolent Society of Ireland.

At the annual meeting of this society held in Belfast on June 16th it was reported that for the past year the total sum raised was £164 6*s.* 11*d.*, and deducting the sum of £3 8*s.* 5*d.* for expenses, £160 18*s.* 6*d.* was forwarded to the central treasurer, being £13 19*s.* 3*d.* more than last year.

Remarkable Transplantations of Organs and Tissues.

AT a meeting of the Academy of Medicine held on June 8th, Professor Pozzi, who had not long returned from America, created some sensation by his account of the remarkable transplantations of organs and tissues accomplished by Dr. Carrel of New York, and already referred to on more than one occasion in your columns. Dr. Carrel, a Frenchman, who commenced his medical studies at Lyons and afterwards proceeded to Chicago, is at the present time one of the directors of the Rockefeller Institute in New York. By means of sutures of extraordinary fineness combined with thoroughly aseptic conditions, he has succeeded in closing severe wounds of arteries, including the aorta [illegible] gaining [illegible] *flambeau.* [illegible] also tran[illegible] carotid a[illegible] portion of the femoral vein, and when the animals on which these various operations had been performed were killed after the lapse of a sufficient interval, it was seen that a complete substitution of one tissue for the other had taken place. Dr. Carrel has found that portions of veins or arteries removed from a living animal can be preserved for weeks and months hanging in a moist atmosphere in sterilised glass tubes hermetically sealed and kept at a temperature of 0° C. These portions of tissue retained their vitality so well that one of them could with complete success be substituted for a corresponding amount of the femoral artery of a living animal. As soon as the suturing was completed, the inserted portion, which had previously been somewhat pale, became pink, and an incision made at the extremity of the limb immediately yielded a drop of blood, showing that the circulation had been re-established [illegible] direction, he repl[illegible] artery taken from [illegible] Professor Pozzi sta[illegible] kidney, and thyroi[illegible] of animals and re-implanted them in a few moments, suturing their principal vessels, with the result that these organs immediately began to act. He has also transplanted entire limbs from one animal to another, replacing the fractured paw of a dog by a paw taken from a different dog. Dr. Carrel considered that there was every reason to believe that similar operations would succeed equally well in the human subject, but he has not yet made the attempt, although several Americans have declared themselves willing to have a missing arm or kidney replaced by one taken from a newly executed criminal.

The International Tuberculosis Society.

In May, 1910, this society, of which Professor Lancereaux is the president, will distribute several prizes and medals to the authors of the best works on the subject of tuberculosis. These awards will include a prize of 300 francs, one of 100 francs, and two of 50 francs each; there will also be two gold and three sil[illegible] by a *diplôme d'honneur.* Int[illegible] or foreign, should send [illegible] envelope to the general secretary, M. Georges Petit, 51, rue du Rocher, Paris.

Treatment of a Case of Slow Pulse.

At a meeting of the Société Médicale des Hôpitaux, held on June 4th, M. Ramond and M. Lévy-Bruhl described the case of a man, aged 31 years, who, after being severely injured by a fall, presented symptoms of slow pulse accompanied by vertigo and attacks of syncope. Before being seen by M. Ramond he had been a hospital patient for long periods and had undergone various methods of treatment without any benefit. The obtaining of a negative result with the atropine test suggested the existence of a lesion localised in the fasciculus of His, and M. Ramond accordingly gave several injections of biniodide of mercury. The pulse-rate rose rapidly from 38 to 44, 56, and at last to 68, the vertigo and attacks of syncope disappearing at the same time, but after somewhat violent bodily exercise there was temporarily a certain amount of vertigo, together with a fall in the pulse-rate to the extent of four or five beats per minute.

Il Congresso Forestale.

THE event of the week has been the Reafforestation Congress at Bologna, an assembly of the first importance for the subject dealt with and the men of authority who intervened. The subject, in varying degrees of interest, appeals to all nationalities. Open a consular report from whatever part of the outlying world, and one cannot fail to find references to the disastrous results of unchecked tree-falling and to the measures, in many cases too late, to retrieve those results. The latest of these, Mr. E. L. Harris's report from Smyrna to the United States Government, tells of Asia Minor what is a thrice-told tale of the Mediterranean countries:—"Much to the detriment of soil and climate...... the trees chopped down are never replanted, and after a few years the mountains, where once stood stately pines and cedars, are covered with miserable scrub and brushwood." Appropriately convened in the noble hall of the Chamber of Commerce, the Bologna Congressisti were fe[illegible] the Minister of Agric[illegible] who went at once to [illegible] the most urgent affl[illegible] floods, the land-slips, the avalanches caused by the ruthless destruction of the woods that once clothed and crowned the hills, bring sudden devastation and misery to the lowlands, making it necessary [illegible] import from countries less [illegible] the material for railways, [illegible] Of this necessity Italy had painful experience after the Siculo-Calabrian cataclysm, when the homeless survivors had to wait for days, nay weeks, in midwinter before the wooden huts could be run up for their accommodation. Passing next to the remedial measures prescribed by this state of things, Signor Cocco-[illegible] past and present, by [illegible] ht to rehabilitate the [illegible] need of better instruction at the two schools of forestry, that of Vallombrosa in Tuscany and Cittaducale in the Abruzzi, and of no less urgent need of a better "forestal service," the present one being underpaid and undermanned, and its surveillance of the forest districts altogether perfunctory. The speech of the day, however, indeed I may say of the Congress as a whole, was that of Italy's greatest financier, a member of the old Parliamentary Right from which her best statesmen have been drawn—Signor Luigi Luzzatti. Deploring that "strage" (tree-slaughter) which has reduced the slopes of the Alps and the Apennines to prairie, and made Italy dependent on foreign countries for timber costing her many hundred million francs a year, the orator plunged into financial proposals by which, where not too late, the means might be found for re-acquiring for the State the control of those denuded uplands, let out in many cases as pasture, and for proceeding to the work of reafforestation inspired by better schools of forestry and officered by a more efficient corps of inspectors. These proposals, carried into law, may take a generation to operate, but "*our sons*," he said, "will enjoy their salutary working in their exemption from floods, from degenerate soil, and the malaria it brings in its train." Hitherto, Italy has been lavishing her energies on the "*symptoms*," not on the "disease"; on the effects, not on the *causa causans.* She spends annually vast sums on embankments of rivers liable to autumnal inundation, till some of these have come to look like overhead canals or aqueducts, while neglecting the reafforestation which is the true preventive. In like manner, to antagonise the malaria-carrying mosquito, she gives money grants for the supply of quinine and wire gauze to the *campagnuoli*, while leaving the soil, with its vegetative energy unutilised, to degenerate under drought and stagnant pools. Italy has begun at the wrong end and cannot too soon return to the thorough systematic cultivation which made her, under the beneficent sway of the Antonines, the happiest of countries—when the Campagna was a smiling garden, or series of farms, with its hillocks discharging their surplus water into *fossae* which in turn debouched into the Tiber. To restore Italy to her long-lost balance between forest-growth and river-flow, from which the soil and its cultivator derive health and prosperity in equal measure—such was Signor Luzzatti's ideal, based on proposals to which the Congressisti could not but give a benevolent adhesion. Other speakers followed, conspicuous among them being the Commendatore Bertarelli of the Italian Touring Club, whose services he volunteered to the Government in the work of propaganda, to bring home to the mountain population the harm done by reckless tree-felling and to aid the "forestal inspector" or engineer in his efforts to preserve what still remains of the ancestral woods. At a subsequent sitting Signor Pini, speaking as a member of the Italian legislature, tabled some useful suggestions for the better organisation and efficiency of the forest *personnel;* and another distinguished parliamentarian, Signor Brunialti, pleaded fo[illegible] studio" of the mountain [illegible] he urged with scientific cogency and expository clearness. On its rising the Congress was entitled to claim for its proceedings a distinct step forward in the realisation of the great problem it has been convened to discuss. It remains for public opinion so to express itself through its legitimate channels, above all at the polling booth, as to leave the Government without excuse for postponing the solution of that problem, as so often previously, to the advent of its successor—in other words to the Greek Kalends!

June 19th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending May 8th show 4279 deaths compared with 4411 in the week preceding. For the same two weeks Bombay Presidency reported 553 against 708, Bengal 319 against 212, the United Provinces 748 against 408, the Punjab 2525 against 2712, Burma 46 against 76, and Central Provinces 75 against 67. Six cases with five deaths occurred in Jammu district, Kashmir, during the week ending May 8th.

The Health of Bombay.

With the arrival of the hot weather the usual improvement in the health of the native population is reported. Cholera has almost disappeared and the general health of the city is once more very satisfactory. The proportion of plague-infected rats has considerably decreased and the incidence of plague itself has again fallen. The total number of deaths reported for the week ending Tuesday, May 11th, was 895, which includes six cases of imported cholera and plague, as against 1053 for the previous week and 905 in the corresponding week of last year. If deaths from plague be excluded the total deaths were 582, which represents a death-rate of only 30 per 1000. The deaths from plague for the week were 313, against 430 for the previous week and 260 for the corresponding week in 1908 and a five yearly average of 475. The number of deaths from small-pox for the week shows a slight increase, 24 against 17 the previous week, 54 the corresponding week last year, and 26 the mean for the last five years. Cholera caused ten deaths, three of which occurred in imported cases.

Popularising Quinine.

The education department has coöperated with the inspector-general of civil hospitals in the Punjab in popularising the use of quinine. In a circular to the inspectors of schools throughout the Punjab the director of public instruction says that he has been informed by the inspector-general of civil hospitals that the widening of the agency for the distribution of quinine has been attended with excellent results, the sales during the year 1908 having far exceeded thos previous years. In view of the common prejudice aga the use of the drug it is suggested that inspecting officer the education department might be invited to coöperate w the officers of the me[illegible]eir effort remove this mistaken [illegible] have b requested when visiting schools to inquire into the arra ments made for the sale of quinine and to urge sc teachers to bring this remedy to the notice of the pe with whom they come in contact. District and assis district inspectors have also been requested to do this.

The New Quarters for Army Nurses at Jhansi.

The quarters for the nursing sisters of Queen Alexand Military Nursing Service for India are nearly completed should be occupied before many months. Jhansi has b in need of lady nurses for duty in the station hospital some years past, and considering the size of the garrison authorities are quite right in supplying the long-felt wa While the army nursing service has been increased out of proportion in the United Kingdom little or no increase been effected in India, where there is really very m greater scope for trained ladies. Successsive princi medical officers on the headquarter staff in Simla h pointed out the numerical [illegible] present nurs service in India, but the [illegible] will not funds for an increase of the present meagre establishment

A Pasteur Institute for Burma.

It has now been definitely decided to build a Past Institute in Burma, and an excellent site has been selec to the east of Maymyo Cantonment on a ridge ab 3650 feet above sea level. The main building of institute and the bacteriological laboratory are to centrally situated in a combined *double-storey bungal* The vaccine department and pathological and parasitologi laboratories are to be single-storeyed bungalows. The cost the entire institute is estimated at Rs.578,229.

The Walker Hospital, Simla.

The Walker Hospital at Simla has now become such indispensable institution that one cannot understand h cases of serious illness among residents in Simla were treat before its foundation. It has a splendid record of succe especially as regards surgical operations, and on the medi side many an enteric fever patient has benefited by careful attendance and skilled nursing obtained in its war The fees charged are moderate, and the income from t source does not go far towards meeting current expens The Indian Government and the Simla municipality ren aid, directly and indirectly, but the financial position h always been rather a precarious one. In the United Kin dom hospitals rely greatly upon regular public subscriptio bequests, and special donations, but in India one cannot lo for any considerable sums of this kind. Patients come treatment from the Punjab, the United Provinces, and ev further afield, but subscription lists for the hospital are known in the plains. In Simla itself there are so ma demands for various charities that both the Walker and Ripon Hospitals fare badly when money has to be collect for them. The question of funds in regard to the former an urgent one and the committee is now considering how can best be met. It is not possible to increase the fee and Government will have to be appealed to for furth assistance. Public entertainments of some kind, such those organised by Lady Collen years ago, may give occ sional lump sums, but a permanent endowment is rea required. At the same time, an active canvass for su scriptions might be instituted, and this should not be co fined to Simla.

Obituary.

Captain C. D. M. Holbrooke, R.A.M.C., died at the Stati Hospital, Wanowrie, Poona, on May 6th, from abscess of t liver. The deceased officer, who was only 30 years old, ha been stationed at Poona for some time, where he was ve well known and popular. The funeral took place the sam evening and was largely attended by the officers of the Poo garrison. Captain Holbrooke entered the service in Januar 1905, and was promoted captain in the Royal Army Medic Corps in July, 1908.

May 18th.

THE DARWIN CENTENARY.

THE Centenary of Charles Darwin, which was inaugurated in his University of Cambridge on June 22nd, is a celebration perhaps unique in the world. If it cannot be said that *mankind from China to Peru is united in honouring the* memory of [illegible] yet a glance at the list [illegible] veral of the *leading* lay [illegible]om countries so far distant the one from the other as Japan and Chile. Darwin's great work of course was not so much the state*ment of the doctrine of Evolution, for that doctrine had* occurred to many minds previously, but the enunciation of the theory of Natural Selection, an explanation of the working of evolution, the honours of which he shared to some extent with Dr. Alfred Russell Wallace. The celebration lasted for three days and showed in a marked manner that, despite the genuine importance attaching to the recent developments of Mendelism, and the remarkable work of Bateson and de Vries, the scientific world accepts the views enunciated by Charles Darwin and regards them as the foundation of modern biology, considering that the theory of evolution by natural selection is still the most valuable weapon with which the problems of biology can be attacked, an opinion that can be shared by many stalwart Mendelians. The applause in the Cambridge Senate House with which the speeches of Lord Rayleigh, Professor Hertwig, M. Metchnikoff, Professor Osborn, and Sir Edwin Ray Lankester were received, shows how firmly the great Darwin is seated on his lofty pedestal.

Tuesday was devoted to the reception of delegates and other invited guests by Lord Rayleigh, the Chancellor of the University. The formal reception at the Fitz-William Museum was of an imposing character, suitable to the magnificent building in which it was held. Lord Rayleigh, wearing his robes of office, scarlet and black, received the *guests of the University, all of whom were wearing academic* dress or uniforms and orders. The museum, rich in the paintings of distinguished British and foreign artists, rapidly filled, and many of the guests streamed out into the adjoining gardens of Peterhouse, thrown open by the Master and Fellows of the senior college. The famous lime-tree avenue and the gardens beyond were decorated with Chinese lanterns, and the paths and flower-beds were bordered with fairy lights. The mixture of robes and uniforms and the dresses of the ladies contributed to make the scene a gorgeous pageant of academic life, linking up the knowledge of to-day with the traditions that go back to the earliest beginnings of the Middle Ages.

Wednesday was occupied with the presentation of addresses, visits of the delegates to various Colleges, the great banquet in the evening, and a garden party given by the Master and Fellows of Christ's College, of which Darwin was a member. At an early hour the Senate House was filled, and the delegates—some 243 in all—were in their places to offer to the University of Cambridge their eulogies of one of her most famous sons. The galleries were occupied by graduates and undergraduates, members of the University, and by ladies. At *half-past ten the audience* rose to welcome the Chancellor, who entered the building with the Vice-Chancellor and the senior and junior proctors, and preceded by the *mace of office*.

Business opened with Lord Rayleigh's address of greeting. After formally welcoming the delegates, he claimed that Cambridge was not held so fast in the bonds of mediævalism as some supposed, for the University was prepared to accept the result of all investigations scientifically undertaken. Darwin, he contended, had made himself beloved by all who had known his character, and was admired by all who *had* even a spark of scientific fire. He hoped that one outcome of the centenary celebrations might be the founding of a School of Genetics, a subject *closely connected* with the work of Darwin and of his nephew, Dr. Francis Galton.

On the conclusion of the Chancellor's speech the presentation of addresses began, and the *delegates as they came up* were received by the audience with applause. Naturally enough, the members of the Darwin family present, Sir George Darwin, Dr. *Francis* Darwin, Mr. William Erasmus Darwin, and Major Leonard Darwin, were accorded an ovation. Among others receiving special recognition were Professor Bateson, Professor Seward, Professor E. van Beneden, Professor Svante Arrhenius, Professor Hoffding, Professor Metchnikoff, Prince Roland Bonaparte, Professor de Vries, Marchese di San Giuliano, Dr. H. P. Keatinge, Sir Richard Solomon, Dr. T. G. Brodie, Sir Robert Stout, Dr. E. Rutherford, Professor A. Sedgwick, Sir Isambard Owen, Sir Archibald Geikie, Sir William Turner, and Professor James Cossar Ewart. The whole ceremony was a succession of brilliant military and diplomatic uniforms and academic robes. The Austrian delegates were in General's uniforms, being given this status by the Austrian Government as a privilege of their position.

The first of the four addresses was delivered by Professor Dr. O. HERTWIG, Director of the Anatomical Institute, Berlin. He pointed out that Darwin's views were more dominant in Germany than in any other country, and showed how they had been championed by Gegenbauer and Haeckel, and how they had formed the starting point for the researches of the younger men [illegible] and others. He concluded b[illegible] celebrations should be rightly [illegible] throughout the world, for Darwin owed his introduction to *science to the friends whom he found at Cambridge.*

Professor METCHNIKOFF emphasised the importance of Darwin's theory on disease. Darwin had made possible the *foundation of comparative pathology.* The whole history of inflammation and of the principle of immunity was Darwinian. [illegible] evolution of resistant strains of bacteria [illegible] In the absence of clear bearings a directing idea is needed to guide one in so obscure a region. Biologists believed that cancers arose from certain aberrant cells detached from embryonic layers, and remaining latent years and decades for the propitious moment to develop in excess. By taking our stand on the theory of the evolution of organisms as formulated by Darwin, the hypothesis to which I have just referred must be rejected. It is well established that embryonic layers were proper to inferior animals as well as to vertebrates and man, and the invertebrates never show the presence of tumours *other than those produced by agents* acting from without. It is therefore very probable that the cancers of man are also due to some cause foreign to the human *organism, in fact, to some virus. This," concluded* Professor Metchnikoff, "is being searched for with avidity, but has not yet been found."

Professor OSBORN of New York referred to the influence that Cambridge has exerted on American thought through the Universities of Harvard, Yale, Princetown, and other universities. A son of Harvard had just succeeded a son of Yale as President of the United States, and thus extended the influence of Cambridge through the Universities. Referring to Darwin's work, he said: "The image rises of a perfected optical instrument in which all personal equation, aberration, and refraction are eliminated, and through which, as it were, we gaze with a new vision into the marvellous forms and processes of the *living world. There* were some," he continued, "impressed by Darwin's grandeur, who thought that they would never get nearer the secret of *life than Darwin had done,* but to accept this idea would mean the abandonment of the progressive leadership of Darwin himself." He concluded by stating that he and his colleagues wished to present to the University a bronze portrait of Charles Darwin that the undergraduates might [illegible] the one [illegible] with- [illegible] *their* judgment, after 50 years of testing [illegible]on, the theory of natural selection remained whole, sound, and con- [illegible] that theory had in any essential [illegible] of muta- [illegible] variations [illegible]in's mind, but modern views which took this standpoint were not, the speaker considered, supported by sufficiently accurate and comprehensive experiments. The Mendelian experiments would have *interested* Charles Darwin, but *they* did not tend to call in question his theory of natural selection. Sir Edwin

Ray Lankester concluded by saying that while Darwin's work remained one of the chief glories of Cambridge all must feel proud of the essentially English character of the man.

Sir ARCHIBALD GEIKIE presented on behalf of the Royal Society a special copy of the Darwin medal, struck in gold. He reminded Lord Rayleigh that he had been secretary of the Royal Society when the idea first originated, and said that it was with the greatest pleasure that he asked him personally to hand it over to the University for its acceptance.

A garden party was held in Christ's College on Wednesday afternoon, which was well attended despite the threatening weather.

The banquet on Wednesday evening was given in the new schools, where covers were laid for 500. The Chancellor was in the chair, being supported by Lord Walsingham, the famous entomologist (High Steward of the University), the Duke of Northumberland, Sir Edward Fry, and the various distinguished delegates.

After the loyal toasts had been duly honoured, Mr. A. J. BALFOUR proposed the "Memory of Darwin." Having referred to his own admiration for Darwin, whom he coupled with those other Cambridge worthies, Newton, Young, Kelvin, Maxwell, and Stokes, he contended that the nineteenth century had borne the heat and burden of the day as far as science was concerned. Darwin's work, he said, was the intellectual heritage of every educated man, no matter what his trade or occupation, and Darwin would stand for all time as the man who had brought about a great and beneficent revolution. He was the Newton of his own broad line of research. He had made greater strides than any predecessor or successor in the study of life, and quite apart from the Origin of Species he had won the first place in the study of natural science. He possessed the skill of an investigator and the mind of a generaliser, and in each capacity had grasped the problems that needed solution. As a man he was never uncharitable or embittered and never ceased to represent fact as fact, despite the storm of obloquy to which his completely revolutionary conception of the world exposed him for years.

Professor SVANTE ARRHENIUS also spoke to the toast and referred to the antiquity of the idea of evolution and to the beginnings of it in the nineteenth century. The patience and impartiality of Darwin, however, had performed the epoch-making work, which extended in its construction over 30 years. He fully realised the far-reaching importance of his ideas, and applied them widely to problems including those of anthropology. The great intellectual revolution due to the introduction of evolution was the most important event in the development of the human mind since the political movement which began with the storming of the Bastille 120 years ago. In conclusion, Professor Arrhenius said: "Let me say that in thus venerating Darwin's memory all men of science regard him not only as an ideal man of science but as a man of science whose power and influence have been enhanced by his integrity and moral worth."

Mr. W. E. DARWIN gave his personal recollections of the great naturalist, his father. He had, he said, an abhorrence of oppression and cruelty, and especially of slavery. Politically he was a follower of John Stuart Mill and Gladstone. Referring to Darwin's neglect of poetry, he deprecated a popular misunderstanding that had tended to cast disrepute on the credit of natural science. He claimed that Charles Darwin could never have written either the closing chapters of the "Origin of Species," or a certain letter to his wife if he had not felt fully the poetry of the world and of life.

Professor E. B. POULTON proposed the toast of "Prosperity to the University of Cambridge," to which the Vice-Chancellor responded.

Later a reception was given at Pembroke College, of which the present Vice-Chancellor is Master.

On Thursday a Convocation for conferring honorary degrees was held and the Rede lecture was delivered by Sir Archibald Geikie, President of the Royal Society of London, the subject being "Darwin as a Biologist," while the afternoon was devoted to a garden party given at Trinity College by Mr. W. E. Darwin, Sir George and Lady Darwin, and other members of the Darwin family.

A lasting memorial has been issued by the Cambridge University Press in the form of a collection of essays called "Darwin and Modern Science," among the contributors to which are the most eminent writers on biology in various countries. The centenary celebration is a curious and striking reminder of the old saying, "Magna est veritas et prævalebit," for some 50 years ago Darwin's views were bitterly attacked, but, as in so many instances, that which was heresy is now orthodoxy, and the celebration this week held in the university of that other great thinker, Newton, is a worthy memorial of one who threw a light upon the dark places of organic life almost equal to that which Newton threw upon the mechanism of the universe.

Obituary.

FREDERICK NUTCOMBE HUME, M.R.C.S. ENG., L.R.C.P. LOND.

THE Metropolitan Asylums Board and the Territorial Forces have lost a valuable officer in the death of Mr. F. N. Hume on June 14th, aged 58 years. He was the third son of the Rev. C. N. Hume, who died just before becoming a centenarian, and was educated at Marlborough College, and then studied for a time at Wadham College, Oxford, until he diverted his attention from the classics to the pursuit of medicine. In 1871 he entered as a student at St. Thomas's Hospital and later became clinical assistant at the Victoria Park Hospital for Diseases of the Chest, obtaining his surgical qualification in 1876. A week later, with a few chosen friends, mostly from his own hospital, the young surgeon found himself at Belgrade and in another week, after surmounting the difficulties of red-tapeism, the small band of English surgeons were in the midst of the Turko-Servian campaign, treating the wounded upon the field, often under the enemy's fire. While so engaged they were absorbed by the National Aid Society, and Mr. Hume distinguished himself above his comrades by the rapidity with which he mastered colloquially the Servian language. At the end of the brief campaign he remained for some months to work in a Belgrade hospital, until lack of British funds caused it to be closed. In July, 1877, he was despatched by the Stafford House Committee to the Russo-Turkish war, and arrived in Turkey in time to witness the defeat of Raouf Pasha's army near Karabounar, and then to be present at the severe fighting of the Shipka Pass, when Suleiman Pasha was hurling the flower of the Turkish infantry against an impregnable position in the Balkans. By the official returns, which were certainly not overstated, 10,000 wounded Turks passed through the ambulance tents during those eventful days, and though there were many doctors on the Turkish side, Mr. Hume and two friends were alone in being capable of performing any surgical operations. When a lull took place in the fighting Mr. Hume retreated with the last of the wounded to some of the hospitals, which were then a seething mass of hospital gangrene, slightly in the rear of the position. But during the early days of 1878 he was back again at the front to take his part in the retreat of the Turkish troops across the Rhodope mountains, on the staff of Valentine Baker Pasha, whose successful defence is well known to military historians. The official report, written by th Stafford House Chief Commissioner of the Turkish arm (Sir V. [illegible]) states: "I wish here to recor the [illegible] on Hume, who, at great persona danger, rejoined his ambulance at Philippopolis by means o travelling along the railway line on a trolley at night, i close proximity to the enemy. He was carrying instruction and a considerable sum of money from Constantinople."

Mr. Hume settled down for some years in general practic in South Kensington, but was again employed by the Nationa Aid Society, in the short Servo-Bulgarian war of 1885, afte which he again acted as director of the English hospital i Belgrade. For his many services he received Turkish and Servian decorations and war medals. Soon after his retur to England in 1886 he rejoined the service of the Metropolita Asylums Board, for which he had already done some temporary work. After serving as assistant medical officer in the South-Eastern Hospital he became superintendent of the Northern Hospital, and eventually held a similar post in the North-Western Hospital, where he obtained the reputation of being one of the best administrators in the service of the board. For some years he was engaged in teaching the subject of fevers to medical students, a work which was very near his

His chief contributions … be found in th… rd. His latest p… and of the Second London Division in the Royal Army Medical Corps (Territorial Forces), where many of the men under his orders were servants of his own board. He threw himself into these new duties with characteristic energy, and on the day before his death marched six miles with his detachment to Bisley, and while so doing felt for the first time the preliminary pains which caused him to suspect the presence of angina pectoris, and from this he died suddenly a few hours later, apparently in his sleep. He was beloved by his friends for many sterling qualities, admired by acquaintances for an exceptional charm of manner, and he now leaves to deplore his death a widow and two sons, both at Westminster School.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Charles B. Porter, Professor of Surgery in Harvard University.—Dr. Saint-Yves Ménard, member of the Paris Academy of Medicine.

Part II.—Charles D. Myles and Dudley F. Torrens.

LITERARY INTELLIGENCE.—Dr. David Forsyth is shortly publishing with Mr. Murray a work on "Children in Health and Disease." The book is stated to present a complete scientific study of childhood, both *normal* and abnormal. After treating of the physiology and psychology of the normal child, the author deals with the health of children in elementary and public schools and with the principles on which the training and moral education of boys and girls should be founded. The State and municipal problems of infant mortality and of the idiot and feeble-… sed in detail. The concluding … e various aspects of disease as … Shaw and Sons of Fetter-… ce the first number of a new medical journal entitled *Heart*, dealing exclusively with the circulatory system, to be issued early in July. The journal is edited by Dr. Thomas Lewis, aided in the selection of papers by Dr. W. H. Gaskell, Professor A. R. Cushny (London), Dr. J. Mackenzie (London), Professor A. W. Hewlett (Ann Arbor), and Professor G. N. Stewart (Cleveland), with the collaboration of other well-known physiologists and physicians It is anticipated that the nature of the material with which the journal proposes to deal, and the standard of the work which it desires to record, will appeal to a large number of readers and contributors, and that those seeking new information with regard to the heart and blood-vessels will find it of special value. One of the main purposes which it wishes to serve is the assistance of workers upon circulatory problems, and those actively engaged in teaching. It will be issued, so far as possible, at regular quarterly intervals, and each volume will consist of four numbers. The subscription has been fixed at 20*s.* per volume, or 5*s.* 6*d.* per single number.—A brief study in the history of medicine is announced by the Oxford University Press. It is entitled "The Last Days of Charles II.," and the primary object of the author, Dr. Raymond Crawfurd, has been to establish the true cause of the monarch's death, which other historians have stated to be apoplexy.

THE twelfth annual dinner of the West London … s held on June 16th …, with Dr. Phineas … of "The Imperial Forces" was proposed by Mr. J. G. Pardoe, and was responded to by Fleet-Surgeon W. H. S. Stalkartt, R.N., now attending the post-graduate course at the West London Hospital. Surgeon-General A. M. Branfoot, I.M.S., also replied, and referred to the benefits which officers of the Indian Medical Service derived from attending the College. The toast of "The Hospital and College" was proposed by the Chairman and acknowledged by Mr. G. F. Marshall for the hospital. Mr. L. A. Bidwell … he College, said that the Post-… in 1896, and since then about … its course of instruction, the entry of new post-graduates last year being 232. The object of the institution was to enable practitioners in the country and abroad to keep themselves abreast with advances in medicine and surgery by attending hospital practice for from one to three months. All the newest methods of treatment were in use at the West London Hospital, and practitioners by seeing these methods applied obtained practical instruction in the way of applying the various new curative agents. The post-graduate students came from all parts of the world, from every colony, and from many foreign countries. A large number of the officers of the Indian Medical Service spent their study furlough at the college, and nearly all the medical officers of the Royal Navy were sent there for their post-graduate courses. Dr. Seymour Taylor submitted the toast of "The Visitors and Kindred Colleges," which was replied to by Sir R. Havelock Charles and Dr. C. O. Hawthorne. Mr. C. R B Keetley gave "The Health of the Chairman," which was duly acknowledged by that gentleman.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—The annual meeting of this association will take place on Tuesday, July 6th, at the Guildhall, London, when a conference of the Poor law medical … of England and Wales, to consider the recommenda-… the Poor-laws and Relief of … Right Hon. the Lord Mayor in …

(4) The Genesis of the Poor-law Infirmary, by Dr. F. S. Toogood, medical superintendent of the Lewisham Infirmary; and (5) The Public Health Aspect of the Report of the Royal Commission, by Dr. G. F. McCleary, medical officer of health of Hampstead. Three of the Royal Commissioners, Mr. Loch, Mrs. Webb, and the Rev. Prebendary Russell Wakefield, are to be at this conference, and it is hoped that as many of the Poor-law medical officers of the country as possible will endeavour to attend, so that the meeting may be representative of the whole service. The special business of the association will take place at 2 P.M., after which any matters postponed from the morning will be continued. The annual dinner will take place at the Waldorf Hotel, Aldwych, London, on the same evening, at 7 for 7.30 P.M., when Surgeon-General G. J. H. Evatt, C.B., the President of the association, will be in the chair. The price of the tickets is *7s. 6d.*, not including wine. Any Poor-law medical officer wishing to be present is requested to communicate with the honorary secretary, Dr. Major Greenwood, 243, Hackney-road, London, N.E Ladies are admissible among the guests. The Lord Mayor and Lady Mayoress have kindly invited Poor-law medical officers attending the conference to afternoon tea at the Mansion House between 3.30 and 6 P.M., the invitation to include ladies.

HOMES FOR INEBRIATES ASSOCIATION.—The report of this association, together with the twenty-fifth annual report of the Dalrymple House at Rickmansworth, prepared by the resident medical superintendent, Mr. F. S. D. Hogg, make interesting reading. Since the foundation of the retreat in 1883, 892 patients have been treated there, and a summary of statistics concerning them is appended. From this summary we learn that 401 patients have been admitted under the Act and 491 as private patients. Under the Act the majority of the inmates have been entered for 12 months and as private patients for three months. The ages of 420 of them have been between 30 and 40, and this we believe is about the age proportion that would have been anticipated. A large number of the patients (218) had no occupation, and among the remainder there were merchants, clerks, and medical practitioners. The medical man, more than the barrister, the solicitor, and the clergyman, seems to yield to the temptation of alcohol or of drugs, though the other professions are also represented. 601 are described as of nervous temperament, 796 had the associated habit of using tobacco, and 286 had had attacks of delirium tremens, one patient having had as many as 13. Spirits were the chief inebriant employed and an exaggerated sense of sociability was the exciting cause in 483 instances. The complicating diseases were, as would be expected, habitual constipation, general debility, and renal disease. Mr. Hogg calculates that during the ten years he has been in charge he has obtained the following results: doing well, about 64 per cent.; improved, about 16 per cent; and not improved, about 20 per cent. Mr. Hogg states that he has as yet discovered no drug which can be substituted suddenly, with safety, for morphia; and as regards the treatment of the morphia habit by combretum, in the first four cases in which he tried the remedy the results were all that could be desired, but subsequent experience has proved that it is only in some cases that this drug is of service. The report is a business-like little record of good work.

MAITLAND SANATORIUM.—A meeting in support of the development of a working colony as an after-stage to the sanatorium treatment provided at Maitland Sanatorium, Peppard Common, Oxfordshire, was held recently at the town house of the Hon. W. F. D. Smith. Mr. Smith, in opening, said the committee asked for £10,000 to provide and partially endow the extra beds required. Sir Richard Douglas Powell said the strength of the cause of which he was privileged to speak on that afternoon lay in the fact that it was no new scheme requiring large outlay in bricks and mortar and secretary's salary, &c., before the first patient could be received, but a scheme already at work, organised seven years ago by Dr. Esther L. Carling and her friends, and which had been at work for the past seven years. Having got the patients into the sanatorium, he said, the difficulty arose how to deal with them so that when they came out from the sanatorium they should be useful members of society. He used to observe that a man went into a sanatorium a human being and came out more or less of cabbage, or rather, in modern-day phraseology, a mollusc. A more recent system of sanatorium treatment had taken a step to improve that condition of things, to redeem the man or woman from the degenerating mental influences of a long system of treatment which used to consist of rest and over-feeding. The problem to consider after the patient had been in the sanatorium for a certain time, and the disease had perhaps been completely arrested, was what next to do for him. If this scheme was successful it might be possible to establish some sort of garden colony on the estate where some of these people could be retained for a longer time and enabled to do some work which would bring some result and yield them perhaps some small return. Such a scheme required much thought. If the public made up their minds that it was right to save these people then their duty went a little further and they must think how to help them afterwards. But at present many who went in very ill came out better but not able to face the strenuous labour of their previous calling. The cause had his most profound sympathy and he heartily trusted that it would be well supported. Dr. S. Davies, medical officer of health of Woolwich, detailed the experience of that borough in sending patients to the Maitland Sanatorium during the past seven years. He advocated the use of sanatoriums to municipal authorities as means of educational treatment, but considered that curative treatment was a matter for charity. He showed that the percentage of "*economic recoveries*" in Woolwich was 5 per cent. greater than that claimed in German statistics. Dr. Esther Carling said the sanatorium colony was needed to carry further the work of educational treatment which municipal authorities began. A children's wing and sanatorium school were also in immediate contemplation.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Men and the Petrol Tax.

THE CHANCELLOR of the EXCHEQUER, according to present arrangements, will receive a deputation of medical men on July 1st in connexion with the taxation on the petrol used in motor cars. Representatives are to be included in the deputation from the medical section of the Motor Union and from the British Medical Association. The case which they will submit to Mr. LLOYD GEORGE is that the petrol tax falls inequitably on medical men, who have to use motor cars in order to reach their patients rapidly. It was thought for some time that the arrangements of the CHANCELLOR of the EXCHEQUER would not enable him to receive this deputation until a later stage in the session, but as the Finance Bill will not be taken on Thursday, July 1st, he has consented to meet it on that day.

The Transmission of Enteric Fever in the Army.

A memorandum by the Director General of the Army Medical Service on the transmission of enteric fever by the "chronic carrier" has been presented to Parliament The subject of "chronic carriers" of enteric fever in the army has several times recently been brought before the attention of the House of Commons by questions addressed to the Secretary of State for War with respect to seven men who have been under treatment at the Millbank Military Hospital. A good deal of misunderstanding existed on the question of "chronic carriers." Accordingly Mr. HALDANE obtained a memorandum from the Director-General of the Army Medical Service. It contains particulars as to the process adopted in the treatment of these men and also charts relating to the subject.

The Inebriate Acts in Scotland.

The report of the inspector for Scotland under the Inebriates Acts for the year 1908 shows that the decline of admissions to inebriate reformatories has continued, but the admissions to retreats have been slightly more than during the previous year. The admissions in the period under review numbered 94 in all. 75 were to retreats, 13 to certified reformatories, and 6 to the State reformatories. The discharges for the year amounted to 133. Of these, 87 were from retreats, 31 from certified reformatories, and 15 from the State reformatories.

Experiments on Living Animals.

The return on experiments on living animals during the year 1908 under licences under the Act 39 and 40 Vict. c. 77 is now available as a Parliamentary paper. Mr. G. D. THANE, the inspector, in his report states that during the year 1908 the total number of licensees under the Act was 453, but 126 of them performed no experiments The number of experiments other than those of the nature of simple inoculations, hypodermic injections, or similar proceedings was 2851. Of these 1452 were performed under licence alone. In this case the animal must during the whole of the experiment be under the influence of some anæsthetic of sufficient power to prevent it feeling pain, and the animal must, if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted, be killed before it recovers from the influence of the anæsthetic. The use of anæsthetics is also required under several of the special certificates. Inoculations, hypodermic injections, and some few other proceedings performed without anæsthetics are responsible for 85,783 experiments. The total number of experiments on animals for the year 1908 is thus 88,634, being 15,230 more than in 1907. Mr. THANE describes in detail the nature of the experiments and points out that a very large number of them are painless. He states that in the event of pain ensuing as a result of the inoculation, a condition attached to the Licence requires that the animal shall be killed under anæsthetics as soon as the main result of the experiment has been attained. Dr. THANE adds that the usual inspections of registered places were made by Sir James Russell and himself. They saw numerous animals under experiment and found the licensees attentive to the requirements of the Act, as well as to the conditions appended to their licences by the Secretary of State. The irregularities which had occurred during the year were few, and all arose from misunderstanding or inadvertence with respect to the extent or application of certificates. By direction of the Secretary of State a suitable admonition was addressed to each of these licensees.

A separate report is made in respect to Ireland by Mr. W. THORNLEY STOKER, the inspector. 20 licences were in force in that country during the year under review, and the experiments performed were 330 in number. The inspector states that the work done in Ireland under the Act was, in his opinion, free from abuse and was sincere and well-intentioned. He attributes the increase in the number of licensees and their experiments to the study of new investigations and treatments of disease by means of antitoxins, sera, and vaccines.

Anæsthetics Bill

Mr. COOPER on June 22nd introduced his Bill to regulate the administration of anæsthetics. It was read a first time.

Nurses' Registration.

One of the obstacles in the way of Bills dealing with the question of the Registration of Nurses has been the fact that rival schemes were in the field. A conference has been arranged between representatives of the organisations interested in the various projects with a view to reconcile points of difference.

Colouring Matter in Margarine.

The Sale of Margarine Bill, which has this week been under the consideration of a Standing Committee of the House of Commons, seeks to prevent the use of colouring matter in margarine so as to give it the appearance of butter. The promoters of the Bill, to which considerable opposition has developed, allege that extensive frauds are being carried out by which margarine is being sold as butter.

Glasgow Hospital for Diseases of the Skin.

The Glasgow Hospital for Diseases of the Skin Order Confirmation Bill has passed through all its stages in the House of Commons.

HOUSE OF COMMONS.

THURSDAY, JUNE 17TH.

The Campaign Against Mosquitoes at Cairo.

Mr. RAMSAY MACDONALD asked the Secretary of State for Foreign Affairs whether [illegible] of Mr. Hugh C.
Ross, steps were [illegible] osquitoes from

which had been [illegible] children wholly or partly [illegible]
in England 230,000 children wholly or partly [illegible]. Of these children 70,000 were in and outside Poor-law institutions.

cottage homes, barrack schools, scattered homes, district schools, and workhouses and infirmaries. A child in a district school cost from 10s. to 13s. 7*d.* per week; in a barrack school from 10s. 4*d.* to 18s. 8*d.*; in a cottage home from 12s. 9*d.* to 25s. 2*d.*; and in a scattered home from 8s. 6*d.* to 11s. 2*d.* He mentioned those figures to show that so far as money was concerned the public benevolence towards the children dependent upon the State was larger and more generous than in any other country in the world. In London 50 per cent. of the "indoor" poor were in specialised institutions, and it had been brought to his attention that 40 per cent. of all the deaths in London took place in public institutions of some kind. From that fact a number of superficial people had deduced a totally wrong theory. Instead of this being taken as a sign of decadence on the part of the community he considered it as being an unmistakable sign of increasing intelligence on the part of the poor themselves by anticipating disease, and when the disease from which they were threatened broke out instead of going to the twopenny or threepenny dispensary doctor they went to these institutions and got the best attention that they possibly could, from the most skilled experts in the various complaints from which they suffered. It had been pressed upon him that afternoon that by taking action on the reports of the Poor-law Commission, the Government, and especially the Local Government Board, might do a great deal by administration. He was delighted to hear so much unanimity upon that point, because when he ventured the other day to suggest hypothetically that nearly all the problems with which that report dealt should be remitted to the Local Government Board he heard suggestions of bureaucracy, and his honourable friend (Mr. Masterman) and he (Mr. Burns) were regarded as oligarchs who wanted to supersede the power of Parliament in settling Poor-law problems. There was much which could be done by administration, and so far as sick children were concerned let him give an illustration. London had 2500 sick children in its workhouses and infirmaries. He and his department were so impressed that this was wrong that they applied to the Metropolitan Asylums Board for an absolutely new institution, which was not being used, which cost £200,000, and which was situated on the breezy downs of Surrey at Carshalton. It was decided to acquire that institution. He was glad to say that 1000 of the 2500 sick children had been transferred from the workhouses and infirmaries into this special institution where the children would be better treated, he believed, at a cheaper cost, because they would recover more quickly at Carshalton than in the workhouses from which they had been taken. If there were any other local authorities who had a similar institution to place at his disposal, he should be glad to take over one, two, or even three more, and he should not rest content until the whole of the sick children in London workhouses and infirmaries, and also in the provinces, were transferred to institutions in which they could be better cared for than they could be in those institutions, however good they might be. Having dealt with the subject of boarded-out children, he said that he proposed to issue an Order to bring the children within the union under the inspection of the Local Government Board inspectors. The community should make the best of the institutions which it had, but it should get rid of ins [illegible] as rapidly as possible. Another question had been rai [illegible] for Bath (Mr. Maclean)—the condition of [illegible] nt of view of sanitary accommodation. The atten [illegible] rnment Board was very properly called to the condition of the [illegible] o-British Exhibition last year, in its sanitary aspect, for the enormous number of people who went there every day and for the staffs who had to minister to their enjoyment. He had promised the honourable Member that he would take action. It was not necessary for the Home Secretary to interfere. Proposals were brought before the authorities of the exhibition and before it closed the situation was considerably relieved. Between the close of the exhibition last year and the present time, he had satisfied himself that the necessary steps had been taken, and at this moment 131 public comfort places had been provided for both sexes. The point had been raised in the debate that so much having been done for the children in the Poor-law schools, it would surely be inconsistent to neglect the larger number of children who were receiving out-door relief. There was something in that point. Honourable members would be pleased to know that the Local Government Board had decided that, so far as the recipients of out-door relief were concerned, the Board would follow up the Tuberculosis notice issued in last January. He ventured to say that fifty years hence the Local Government Board would be credited, for having issued the Tuberculosis Order, with having done a great deal to mitigate the spread of the disease and a great deal for public health. By that Order and by regulations and by bringing children within the purview of attention, he believed a great deal would be done to diminish tuberculosis and other diseases. The right honourable gentleman went on to say that the Notification of Births Act had been adopted by 140 towns and boroughs. The Registrar-General said that 84 large towns had adopted it, and that of the 140 which had altogether adopted it, 18 were metropolitan boroughs. The City of London had adopted it, and he was pressing the remainder of the metropolitan boroughs to adopt it. If they did not do so he should have to take steps to force them, but he sincerely hoped that such a course would not be necessary. There had not been sufficient experience of the Act to enable him to give statistical details, but he was convinced that the Notification of Births Act and the regulations dealing with tuberculosis and those relating to outdoor relief would do a great deal of good towards stopping some of the worst diseases. It had been suggested that in addition to what was being done to meet the ravages of tuberculosis, the Local Government Board should issue more circulars. It had sent out several memoranda which had been issued to all sanitary authorities. If it was necessary to extend the system of education to all local authorities he would consider the best way in which that could be done. That brought him to another point which had been raised by several members, and it related to the question of infant mortality. The committee would be pleased to know that the general infant mortality of the whole country had shown a direction downward. The rate had fallen from 140 or 150 to 113 throughout the whole country. He believed that the steps which had been taken through the Notification of Births Act would tend still more to the rapid diminution of infant mortality. Unfortunately, in some of the midland and northern towns, where, in his judgment, too many married women went to work under conditions and at a time when they ought to be at home, and frequently resumed work when they should be nourishing themselves and sustaining their children by natural means, the infant mortality was still too high. That aspect of infant mortality had not been raised that afternoon. What had been raised had been the infant mortality with which the Local Government Board could deal, and both the honourable Members for Bath (Mr. Maclean and Mr. Gooch) would be pleased to know that the infant mortality with which they had dealt—viz., the infant mortality in workhouses and infirmaries—was being dealt with. The medical department of the Board was going to follow up the excellent report on Public Health and Social Conditions which had recently been issued, and intended to produce a special report on infant mortality viewed from several aspects which had not been dealt with in the past. That inquiry was now going on and the excellent books which had recently been published would be supplemented by a special report on the investigation into infant mortality. He sincerely trusted, as far as that was concerned, the investigation and the report would satisfy the honourable Members. It was only fair that he should deal with one suggestion made by one honourable Member, and that was as to the death-rate that happened occasionally—he admitted too frequently—in some of the worst districts in the workhouses and maternity wards and infirmaries. It was only right that honourable Members should temper their reception of certain allegations made recently in various newpapers by a knowledge of facts and circumstances as to the death-rate of infants born, often to women who had been cruelly treated and beaten, overworked, and badly cared for, before they came into the workhouse, and very often absolutely in the process or immediately before the act of childbirth itself. It stood to reason that a child whose father and mother were living under these bad conditions could not be expected to live, or if it lived, to be as strong as children differently placed. Where 60 per cent. or 70 per cent. of the women who were in the maternity wards in London and workhouses were illegitimate mothers, as against only 4 per cent. of illegitimate mothers outside, it stood to reason that the children who were the offspring of such women could not expect to live, or if they lived, to be as strong as the children of legitimate parents. The honourable Member for Merthyr Tydvil (Mr. Keir Hardie) shook his head at that statement. Did the honourable gentleman agree with Savage the poet, who himself was illegitimate, that illegitimate children were the sickly fruit of fond compliance? No, he could not. Did the honourable Member take the converse view that illegitimate children, according to the same poet, were stamped in the mint of nature's glowing ecstasy? Certainly not. What were the facts? The facts were that illegitimacy not only connoted moral delinquency, but also indicated physical degeneracy.

Mr. JOHN WARD: Nonsense.

Mr. BURNS: If honourable Members will do me the honour of going with me to some of the maternity wards in London workhouses and see poor children, the offspring of illegitimate mothers, they will see how disease, lack of food, overwork, and brutal treatment have destroyed the power and capacity of the illegitimate child to resist disease. They would see how very difficult it was to rear illegitimate children born under such conditions, and that was proved by the fact that the extent to which workhouse mortality amongst infants was greater than outside was apparent only in the first week, because after the first week, when good treatment, good food, good nursing, and regular medical attention were always available, the child got into a healthier condition and improved very rapidly. The Local Government Board was giving further attention, as far as it possibly could, to this matter, and he was convinced that the mortality of children outside workhouses and inside them would never be materially reduced until the pre-natal conditions of the child, the conditions of the mother long before the child's birth, were enormously improved; and it was the business of every employer of labour, of every husband and wife, and of every department and authority concerned in the future of the race, to see that the pre-natal conditions of the child were vastly improved, and that the mother while carrying the child should be relieved from brutality and overwork, conditions which left on the child an impress for long years after it had left either the home, the workhouse, or the infirmary. The right honourable gentleman also dealt with the question of the adulteration of butter. He said that the Butter and Margarine Act of 1907 would be administered principally by the Board of Agriculture and Fisheries, but under it certain powers were given to officers of the Local Government Board. If honourable Members turned to the last report on this subject they would find that in 1907 93,716 samples were taken in England and Wales, and the great bulk of them were for butter, milk, or margarine. In 1908 the number of samples had increased to 96,249. In Scotland 8576 samples were taken in 1907 and 8827 in 1908. In all the United Kingdom it was safe to say that over 100,000 samples were taken. Prosecutions had been entered upon, and in many cases very heavy fines, and in one or two cases imprisonment, had been meted out to those guilty of palming off upon both rich and poor food other than what food really ought to be. The Local Government Board incurred a great deal of unpopularity and had very great difficulty in getting the Food Regulations Act through a year ago to give wider powers to stop the sale of unsound food. Honourable Members could rest assured that he was anxious to protect the food of the poor. If the honourable Member (Mr. Kilbride) would only take the trouble to look at the reports of the Local Government Board and the Board of Agriculture and see the enormous number of prosecutions, he would find that his (Mr. Burns's) department was not at all anxious to allow the man who "fobs off" on the poor margarine for butter, or what was equally bad, rancid instead of fresh butter, to escape. There was no present local or administrative power which the Local Government Board now had that it would not be willing to exercise to the fullest to prevent under the Food and Drugs Act, the Butter and Margarine Act, and the Food Regulations Act either adulterated or impure food being sold. The right honourable gentleman further stated in regard to vaccination that in 1905, 4 per cent. of the children born were exempted; in 1906, 5 per cent.; and in 1907, 6 per cent. Mainly as the result of the Act which he piloted through the House two years ago the 6 per cent. of 1907 was raised last year to 17·2 per cent.

The amendment having been withdrawn, the vote was agreed to.

MONDAY, JUNE 21ST.

The Water-supply of Vatersay.

Mr. COCHRANE asked the Lord Advocate whether his attention had been drawn to the reports of the medical officer of health and the county sanitary inspector for Inverness-shire condemning the water-supply of Vatersay as being insufficient for 60 crofter families and liable to serious contamination; and what steps the Congested Districts Board intended to take to give to their proposed new settlers an adequate water-supply free from any risks to health.—Mr. URE replied: I am aware of the [illegible] ined [illegible] ture [illegible] th a [illegible]

THE HUMOURS OF PARLIAMENT.

THE following delightful passage appeared on the question paper of the House of Commons for June 16th:—

> 14. Mr. Leverton Harris,—To ask Mr. Chancellor of the Exchequer, which of the following substances when found in Great Britain are to be considered minerals within the meaning of Clause 12 of the Finance Act: abriachanite, acanthite, acmite, actinolite, adamite, adinole, adularia, ægerine, æschynite, agalmatolite, aikinite, alabandine, alabaster, alalite, albertite, albite, alexandrite, algodonite, allanite, allemontite, allochroite, allomorphite, allopalladium, allophane, almandine, alstonite, altaite, alum, aluminite, alunite, alunogene, amalgam, amazonstone, amber, amblygonite, amblystegite, amethyst, amianthus, amphibole, amphodelite, analcime, anatase, anauxite, andalusite, andesine, anglesite, anhydrite, ankerite, annabergite, annerodite, annivite, anomite, anorthite, anthophyllite, anthracite, anthraconite, antigorite, antimonial nickel, antimony, apatite, aphrite, aphrodite, apophyllite, aquamarine, aragonite, arcanite, ardennite, arfvedsonite, argentite, arkansite, arksutite, arquerite, arsenic, arseniosiderite, arsenolite, asbestos, asphaltum, astrakanite, astrophyllite, atacamite, atopite, augite, aurichalcite, avalite, aventurine, axinite, and azurite.

We feel constrained to point out for the information of Parliament that aurichalcite has nothing to do with gold. The word is properly spelled orichalcite, Gr. ὀρείχαλκος. Chemically it is a hydrous zinc copper carbonate $H_6\,(ZnCu)_5\,C_2\,O_{12}$.

METALLIC CONTAMINATION OF TINNED FRUIT.

A PROMINENT feature of Mr. W. F. Dearden's last report to the port sanitary authority of Manchester was the number of tons of preserved fruit seized and condemned on account of metallic contamination. The seams of the tins had been sweated and re-soldered, with the result that a considerable amount of solder had become exposed to the action of the acid contents, and in many cases there were so many pellets inside that the tins rattled like money-boxes. Lead and tin were found in all the samples forwarded to the Public Health Laboratory. *The tomatoes contained as much as 1·20 of a grain per pound.*

DEAFNESS AND BATH TOWELS.

A CORRESPONDENT writes that she considers she has found "the solution of the increasing cases of deafness." She thinks it due to the use of bath towels with which, she argues, it is impossible for the bather to dry the ears, whereas the old-fashioned fine towels allowed the inside of the ear to be dried. There may be something in our correspondent's idea, but surely it is quite simple for anybody to use both a fine towel and a bath towel, or if they do not possess the former article such a simple thing as a handkerchief or even a piece of soft paper will serve admirably as a means of drying the external meatus.

AN EXPIATORY SACRIFICE.

Mr. E. O. Blech, British Consul for the district of Jerusalem, reports that in 1908 public health remained good, but there was an epidemic of cerebro-spinal meningitis, confined almost exclusively to the poorer class of Jews, from which many deaths occurred, about 12 per cent. of the cases being fatal. "It is characteristic," adds Mr. Blech, "that as a means of averting this disease recourse has been had to the strange plan (followed, it is said, during a cholera epidemic 50 years ago) of marrying one or several couples of pauper Jews, who have been provided with an outfit and a living allowance for a certain period at the cost of the community. These marriages take place in the Jewish cemetery and are looked upon as a kind of expiatory sacrifice."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.
